Inaugural Address

ON THE

MEDICAL NEEDS OF INDIA.

Delivered at the London School of Medicine for Women on Oct. 1st, 1913,

BY SURGEON-GENERAL SIR CHARLES PARDEY LUKIS, K.C.S.I., M.D. LOND., F.R.C.S. ENG.,

DIRECTOR GENERAL, INDIAN MEDICAL SERVICE.

DR. GARRETT ANDERSON, LADIES, AND GENTLEMEN,—I have in the first place to express my sense of the honour done me by your council in asking me to deliver the inaugural address this afternoon, and to say how very pleased I am to be able to accept the kind invitation extended to me. The subject which I have selected is the Medical Needs of India, my reason for this choice being that in my opinion one of the most urgent needs of India at the present time is an adequate supply of suitable and fully-trained medical women.

The problems connected with the preservation of the public health in India are extremely complex, especially as regards the remedying of sanitary defects, the education of the people in personal and domestic hygiene, the saving of infant life, and the protection of women from the dangers incidental to childbirth.

SANITARY QUESTIONS: MALARIA, PLAGUE, AND TUBERCULOSIS.

The time at my disposal being limited I do not propose to-day to deal with the larger sanitary questions. Neither is it necessary that I should do so. Under present conditions such questions are outside the scope of the work of the medical woman in India. I must, however, say a few words on the subject of the education of the Indian public in personal and domestic hygiene, because it is the prejudices of the vast majority of the populace, their conservatism, and their suspicion of any innovation or change, which constitute such a formidable obstacle to rapid progress in medical or sanitary matters. In order to illustrate my point let us consider briefly some of the conditions influencing the spread in India of those three deadly diseases—malaria, plague, and tuberculosis. Malaria, as you know, is conveyed from man to man by certain species of anopheline mosquitoes. For a long time it was thought that all malaria arose from swamps, but recent observations have shown that this is not the case. Thus the researches of Liston and Bentley have proved that the severe epidemic of malaria from which Bombay city has suffered of recent years does not arise from the surrounding swamps, but is conveyed by a species of domestic mosquito which breeds in the wells attached to private houses. Similarly, much of the malaria which occurs in up-country stations is due to the breeding of mosquitoes in collections of stagnant water in and around habitations. It is obvious, therefore, that the attempts of Government to stamp out malaria are apt to be nullified if householders refuse to close down private wells, which are a danger to the community, or persist in allowing broken earthen pots, old kerosene oil tins, &c., to accumulate in their yards and thus furnish breeding grounds for mosquitoes.

Then again, as regards epidemic plague, the history of which as it occurs amongst human beings is as follows. Plague occurs amongst the rats in a house. So soon as the rats begin to die the remainder at once migrate from the infected spot, but they leave behind them their nests, and in these nests are a large number of rat-fleas which contain plague bacilli owing to their having sucked the blood of infected rats. Presently these fleas become hungry, and, finding no rats, they sally forth and bite human beings, thus infecting them with plague. The question of the prevention of plague is therefore chiefly one of domestic hygiene, and it is essential that the public should realise the danger of permitting collections of rubbish in and about their houses behind which rats can build their nests. They should be taught also not to throw about in the vicinity of their houses remnants of food which will attract rats, and, in fact, every precaution should be taken to prevent the rat from becoming a domestic animal. The rat is not a domestic animal in the houses of Europeans in India, but it is a domestic animal in the houses of a large number of Indians, and this I believe to be the explanation of the difference in the plague-incidence on the two races.

I now come to the subject of tuberculosis. Nowadays there is a great boom in tropical diseases, and it is right that there should be, but one ill effect of this is that it is apt to distract attention from diseases which, although not, strictly speaking, tropical in origin, nevertheless create enormous havoc in tropical countries. The chief of these is tuberculosis, the mortality from which in some of our larger native cities exceeds that of either Birmingham or Glasgow. Tuberculosis in India, however, differs from that disease in England in one striking particular—it is invariably of human and not of bovine origin. For this there are two explanations: the first is that Indian cattle are practically free from tuberculosis. When I made this statement at the recent Conference on Infant Mortality it was received with a certain amount of scepticism, but I am glad to learn from competent observers that similar conditions prevail both in Ceylon and in the Malay Peninsula. The second explanation is that Indians never drink unboiled milk—consequently milk may be regarded as a negligible factor in the spread of tuberculosis in India; and the disease is always conveyed by human agency as the result of defective ventilation, overcrowding, and indiscriminate spitting. The Government and the local authorities are doing all in their power in the matter of town planning and the provision of sufficient light and air in tenements, and by the prohibition of expectoration in public places, but their efforts will be of little or no avail until the Indian public learn the danger of sleeping in closed rooms and of permitting indiscriminate spitting within house limits.

THE TEACHING OF PERSONAL AND DOMESTIC HYGIENE.

Hitherto the teaching of personal and domestic hygiene in India has been very unsatisfactory. It has been regarded merely as a school lesson to be learnt by rote, and I doubt very much whether the scholars attach any importance to it or regulate their lives by its precepts. You may, for instance, hear a boy state in school: "I must eat clean food: I must drink pure water," and then as soon as school is over he will scamper off and eat sweetmeats from a fly-infested open stall in the bazaar, assuaging his thirst with a draught of water from the village tank, which is indiscriminately used for drinking purposes, for bathing, and for the washing of clothes.

Efforts are now being made both by Government and by the St. John Ambulance Association to render instruction in hygiene more practical by means of lantern demonstrations, popular lectures, and the distribution of illustrated leaflets, but even if these efforts are as successful as it is hoped they may be, they will not reach the root of the evil, for they will only instruct the men of the community. This is my reason and excuse for bringing the matter to your notice to-day. Ladies who have spent all their lives in England are apt to regard their Indian sisters as being very downtrodden and oppressed. This is a grave mistake. Out of doors the man is lord of creation, but once he is inside the house he is absolutely controlled by his wife and mother in all matters concerning domestic economy and the family life. Indeed, I know of no country where the woman is more absolutely the mistress of the house than she is in India, and I am convinced that we shall never make any real headway in promoting the knowledge of domestic and personal hygiene until we have convinced the women of India as to its necessity, and they have thrown their powerful influence into the scale. Here the medical man is powerless—the *purdah* bars the way, and it is to the medical woman that we must look for educational propaganda inside the zenana.

I have dealt with this subject at some length because I wish to lay stress upon the fact that the work of medical women in India should not be confined merely to the care of women and children. They may do admirable pioneer work by disseminating knowledge of the laws of health and the value of preventive measures, thus conferring an incalculable boon upon the populace as a whole, both by showing them how to prevent the spread of communicable disease, and by teaching them how to increase the natural powers of resistance against pathogenic germs.

INFANT MORTALITY.

The subject of infant mortality in India has of recent years attracted considerable attention. That it is a subject imperatively demanding such attention cannot be denied. In 1911, 4,752,152 male children and 4,457,551 females were born in India, and in the same year the actual number of deaths of children under one year of age was 1,016,823 males and 873,677 females; that is to say, roughly speaking, about one-fifth of the children born died within the first year of their life. It is very difficult to arrive at the actual causes of this high rate of mortality. The figures at our disposal are often of doubtful accuracy, and the comparison of figures from different localities is most fallacious. A relatively high reported death-rate frequently means merely that the registration of vital statistics in this particular locality is carried out more satisfactorily than in some other place with a more enviable but totally undeserved reputation, and one of the greatest of our present necessities is an improvement in our methods of collecting vital statistics. In most of the large cities and towns of India the number of births and deaths reported probably approximates to the truth, but with regard to the causes of death even approximate accuracy is rarely attained. This is inevitable when the diagnosis of the cause of death is in the vast majority of instances made by persons with no medical training. Moreover, when death is due to infectious disease wilful concealment frequently occurs.

As the result of inquiries made in four large towns in India, Major Robertson, the Sanitary Commissioner with the Government of India, is of opinion that the causes of infant mortality, taken in the order of their importance, may be classified under four headings: (1) Malaria, operating both directly on the infant and indirectly through the mother; (2) diseases due to insanitary surroundings; (3) diseases due to ignorance on the part of the mother with regard to the feeding and care of the infant; (4) accidents of childbirth and diseases attendant thereon.

As regards the last two groups, I believe that early marriage is very largely responsible for the high rate of infant mortality in India, where marriage is almost universal and at the earliest practicable age; and there can be no doubt that much of this mortality is due to the ignorance and immaturity of the mothers. The instruction of these young mothers, therefore, in all matters connected with antenatal and postnatal hygiene is a point deserving of consideration by all medical women practising in India.

Another adverse factor vying in importance with that of early marriage in determining the excessive mortality is to be found in the primitive methods of midwifery almost universally in vogue. Not only do such methods lead directly to the death of the infant from tetanus and other infections, but they also indirectly increase the infant mortality by depriving the children of their natural nourishment, for it must be remembered that, owing to the unsatisfactory substitutes given as food to children deprived of their mothers' milk, the death of the mother, or even the drying up of her milk as the result of sepsis, in the majority of cases practically seals the fate of the child. I need not dilate upon the suffering and loss of life which result from these primitive methods of midwifery. As you probably are aware, in India the deaths in childbed are about three times as numerous as they are in England. The only remedy for this deplorable state of affairs is that medical women, by their precepts and practice, should create confidence in modern midwifery and devote themselves to the systematic instruction of the native midwives.

THE WOMEN'S MEDICAL SERVICE FOR INDIA.

I think I have said enough to bear out my opening statement that one of the most urgent needs of India at the present time is an adequate supply of suitable and fully trained medical women, and I now pass on to the consideration of the manner in which it is proposed to supply this need.

The work of supplying female medical aid to the women of India is chiefly performed by two voluntary agencies—that of the missionaries and what is generally known as the Lady Dufferin Association. Of late years the work of the latter association has been subjected to much criticism, and there can be no doubt that the conditions of service have not been such as are calculated to attract the right stamp of medical woman. Various complaints have been made, especially as regards subordination to men, liability to sudden dismissal, absence of incremental rates of pay or provision for retirement, or any definite rules as regards furlough and study leave. I do not propose to enter here into the controversy that has raged round this subject, but I shall merely state for your information the manner in which it is now proposed to redress the legitimate grievances and improve the position of medical women serving under the Dufferin Association.

In the first place, it may be as well to mention that the Government of India have decided definitely against the creation of a State service of medical women; they have, however, approved of a grant of £10,000 per annum for a service of medical women under the Central Committee of the Dufferin Association. This service will be called "The Women's Medical Service for India," and I have received the permission of the Central Committee to sketch out for you in outline the conditions of service which received final sanction at the meeting held in Simla early last month.

The service in the first instance will not exceed 25 first-class medical women, one-fifth of whom will constitute a leave reserve. Its members, subject to certain provisions, which I will mention later on, will be under the direction and control of the Central Committee of the Dufferin Association. I may mention here that there is already one medical woman serving on this committee, and that the question of adding a second is now under consideration. Recruitment for the service will be made in two ways: (*a*) *In India*, by a medical subcommittee of the Central Committee which shall include the Director-General of the Indian Medical Service, the Surgeon to His Excellency the Viceroy (who is also the honorary secretary to the Central Committee), and a first-class medical woman. (*b*) *In England*, by a subcommittee consisting of a medical man and two medical women conversant with Indian conditions, to be nominated by the Home Committee of the Dufferin Association. Such subcommittees will perform the duties of a Medical Board, examine candidates for physical fitness and give permission to return to duty after invaliding, and in India the subcommittee will have power to appoint temporary local boards in cases of emergency.

The central committee will decide what proportion of the members of this service shall be recruited in England and in India respectively. In the original constitution of the service duly qualified medical women who are already in the service of, or who have rendered approved service to, the Dufferin Association will have first claim to appointment, and thereafter special consideration will be paid to the claims of candidates who have qualified in local institutions and of those who are natives of India.

All newly appointed members of the service must be British subjects. They must be not less than 24 or more than 30 years of age at the time of recruitment, and they will, except under special circumstances, be retired on attaining the age of 48. They must possess a medical qualification registrable in the United Kingdom under the Medical Act or an Indian or colonial qualification higher than the L.M.S. and they must produce certificates of health and character. They will engage for general service anywhere in India or Burma, and they will then be appointed by the central committee to serve in different provinces. On first appointment they will serve a period of probation in one of the larger hospitals, extending in the case of those recruited in England to six months and in the case of those recruited in India to three months. At the end of such period of probation their appointment will be confirmed or terminated, as the case may be, by order of the central committee, and after confirmation service will be terminable at any time by three months' notice on either side.

Members of the service will receive a salary of Rs.350 per mensem during their period of probation, and thereafter a salary of Rs.400 from the first to the fourth year inclusive, Rs.450 from the fifth to the seventh year, Rs.500 from the eighth to the tenth year, and Rs.550 after the tenth year, but no member will be confirmed in the Rs.400 grade unless she passes her examination in the vernacular within one year of her appointment. In addition suitable quarters will be provided free of rent, or house rent will be given in lieu thereof. There will also be a provident fund as a provision for retirement. Members of the service will draw travelling allowance at the usual rates, and they will be entitled, in addition to the usual privilege leave, to eight months' furlough after four years' service and to study-leave up to nine months. Whilst on furlough they will draw half-pay and two-thirds whilst on study-leave. They will be permitted to engage in private practice, provided that such private practice does not interfere with the performance of their official duties.

When members of the service are appointed to provinces they will forthwith become subordinate to the provincial committee which shall have powers of punishment, including suspension, but the power of removal from the service or dismissal for inefficiency, misconduct, or other valid cause, will be vested absolutely in the central committee. Any member of the service who has been recruited in England, in the event of non-confirmation at the end of the period of probation or on removal or dismissal, will receive a sum sufficient to cover her return journey to England. Every hospital will be in charge of a local committee, and the medical woman in independent charge of such hospital will be entitled to attend all meetings of the local committee. She will have full professional control of her hospital and such powers of administrative control as may be determined by the authorities financially concerned. She will not be under the civil surgeon in any way, but should she wish to do so, she can always call him in for professional assistance or consultation.

As regards the inspection of women's hospitals, it is proposed to associate with the Inspector-General of Civil Hospitals one of the senior medical women in each province, who will receive extra pay and travelling allowance for this purpose, but she will not be a full-time officer. She will make her visits of inspection in addition to any which the Inspector-General of Civil Hospitals may think fit to make himself, due regard being paid to *purdah*. She will also be expected to give sympathetic judgment, opinion, and advice to the younger women in charge of hospitals. It is proposed also that the inspection of the minor female branch dispensaries shall be entrusted to the medical woman in charge of the large hospital at the headquarters of the district concerned.

Lastly, the central committee, who will now be mainly responsible for the salaries of the medical women of this service, hope that the provincial committees will devote the funds they will thus save to increase their staff of female assistant surgeons, who will work as assistants to the medical women in charge of the larger hospitals.

REMARKS ON THE SCHEME.

This, ladies, is the scheme, which I think you will agree redresses all legitimate grievances and gives the medical woman in India an assured and definite position. It requires no further explanation on my part, but I should like, with your permission, to reply to one criticism that has been made on it, and also to offer a word of advice to any candidate who may think of entering the new service. The criticism to which I refer is to the effect that the rate of pay on first joining is inadequate, and that it will not attract the right type of woman. In reply to that I would point out that when you take into consideration the free house, the terms are better than those offered to young officers of the Indian Medical Service. Moreover, from the very beginning the medical woman has the opportunity of private practice, whereas the young officer of the Indian Medical Service spends his first five or six years in military employ, where he can have little or no private practice, whilst he has in addition all the expenses incidental to regimental life.

My word of advice refers to this same question of private practice. If you wish to be of real service to your poorer patients and also to be a successful practitioner amongst the better classes I recommend you to devote your six months of probation not merely to the study of tropical diseases, but also to learning the language and to making yourself acquainted with the customs and prejudices of the country. Learn to speak Hindustani as it is spoken by educated Indians; be not content with the horrible jargon that the average European uses in conversation with his servants. Study, moreover, Indian prejudices, especially as regards rules of diet in connexion with illness. If you fail to do so, much trouble awaits you. When you are called in to see an Indian patient, after the diagnosis, prognosis, and treatment have been discussed, the last question that will be put to you is, "What about diet?" If then you order an article of diet which according to Indian ideas is contraindicated in the class of disease with which you are dealing; if, for instance, you commit the horrible blunder of ordering milk in a case of bronchial catarrh, or rice for a patient suffering from malarial fever, the chances are that so soon as your back is turned your prescription will be torn up and you will never be called in again by that family. Above all, do not fall into the grievous error of regarding these prejudices as nonsensical. The longer you live in India and the more intimate your connexion with Indians the greater will be your appreciation of the wisdom of the ancients, and the more completely will you realise that the West still has much to learn from the East.

A few more words and I will bring this long discourse to a close. It is obvious from what you know of the size of India and from what I have told you as regards the medical needs of that vast continent, that these needs cannot be supplied merely by European agency, whether it be that of medical men or medical women. If, therefore, female medical aid to the women of India is ever to become a reality it will be necessary to utilise indigenous talent, and one of the most important duties of the new service of medical women will be to train Indian women and domiciled Europeans and Anglo-Indians for the profession of medicine. Hitherto, owing to the absence of a medical school exclusively for women, it has been practically impossible to obtain Indian women of a suitable class, but this difficulty has now been overcome. Her Excellency Lady Hardinge has collected a very large sum of money which will suffice for the construction and equipment of a thoroughly up-to-date medical college for women, attached to which will be a female hospital of about 150 beds and a training school for nurses. The Government of India has given an excellent site on the new Imperial enclave at Delhi, within half a mile of the railway station. We hope also to obtain a grant sufficient to cover the annual upkeep. This college will be entirely staffed by women, and it will offer to the new service of medical women opportunities for professorial, tutorial, and research work which they could not obtain in private practice. The construction of the college will commence very shortly, and the committee of management will consist of three women and two men. Meanwhile medical women are being, and will be, largely consulted as to its organisation, and it is proposed to appoint the lady principal a year before the college is opened in order that she may supervise the construction and superintend the arrangement of the fittings, equipment, and furniture.

I have said enough to show not only that India is in urgent need of the services of medical women, but that, under the improved conditions, it offers a splendid career to medical women of the right stamp.

I will not detain you, therefore, any longer, except to express the great pleasure it gives me that this scheme has materialised during my term of office as Director-General of the Indian Medical Service. Believe me, ladies, the members of the service which I represent are not hostile to the interests of medical women; on the contrary, we are your sincere well-wishers, and I feel very strongly that we have not deserved many of the bitter attacks which have been made upon us in recent years. India affords ample scope for physicians and surgeons of both sexes, whether they be officials or independent practitioners, and I trust that in the future the medical woman, now that all irksome restrictions are about to be removed, will cease to regard the civil surgeon as her natural enemy and will learn to look upon him as an esteemed friend and colleague, and that in the days to come medical men and medical women practising in India will work in complete harmony to their mutual advantage and that of suffering humanity.

ROYAL SANITARY INSTITUTE.—A British Columbia branch of this institute was formed in Vancouver in August. Lectures were given last winter, and it is hoped to continue the courses this year under the auspices of the institute. Dr. F. T. Underhill, medical health officer of Vancouver, is the chairman for the year, and Mr. R. Robertson the secretary and treasurer. There are 29 Fellows, Members, and Associates in British Columbia, and there is plenty of work before the branch.

Introductory Address

ON

MEDICINE AS A LIBERAL EDUCATION.

Delivered at the Opening of the Winter Session of the Medical School of the Middlesex Hospital,

By W. SAMPSON HANDLEY, M.S. Lond., F.R.C.S. Eng.,

SURGEON TO OUT-PATIENTS AT THE HOSPITAL.

Gentlemen,—My first duty—a very pleasant one—is to say a word of welcome, brief but hearty, to those who have just joined us, the new students. They may be feeling a little strange and a little lonely. Let me then assure them that to-day by joining the hospital they have made many friends, and that we older Middlesex students, their teachers, give them a warm welcome. We desire them to feel that they can talk to us freely about their difficulties in the present and their hopes and plans for the future. Potentially, they are the most important people present to-day, for to them it will be given to guard the traditions and to mould the future of this hospital. We are proud of our past, but we think more of our future, and we see it visualised in the men who have just joined us. The buildings in which Charles Bell, Thomas Watson, and Burdon Sanderson taught were full of memories, but they are disappearing, so that a new building may arise better suited to modern needs, and especially to modern methods of research. Let me tell the men who will inherit that building that the hospital demands of them their loyalty and service. It bids them cease to be isolated individuals and become members of a commonwealth, wheels in a vast machine, and parts of a great whole. The fulness of their response to that appeal will be a measure of the future greatness of the hospital, and of their personal happiness while they work within its walls.

Distinguished Men who Forsook Medicine.

In the brief time at my disposal I propose to draw your attention to the careers of some distinguished men who, after commencing life as doctors, have adopted another profession. My object in doing so is to show you that medicine is not a mere technical training, but that it forms one of the best means of developing a man's powers in whatever direction those powers are later to be applied. In other words, a medical training is a liberal education. The lifelong exercise of the art of medicine may tend ultimately to narrow the outlook, but this is an entirely separate question which does not now concern us. It occurred to me that if some of the distinguished renegades of medicine could be induced to collaborate in writing my address for me I should be doing a kindness both to my audience and to myself, while at the same time I could reserve to myself the sole merit of the authorship of their joint production. I regret to say that this well-conceived design has miscarried. I can, however, give you several authoritative estimates from men educated in medicine of its influence upon their subsequent non-medical career. Of such men the great historical prototype is the patron saint of medicine, St. Luke, the beloved physician, the biographer of his Master. Doubtless there are many men who, like St. Luke, have abandoned medicine for the ministry. The recent history of this hospital supplies an example in the person of Canon Arnott, now, and for the past 28 years, rector of Beckenham, who is a Fellow of the Royal College of Surgeons, a distinguished pathologist, and the author of a work on cancer. Canon Arnott was formerly on the staff of this hospital as assistant surgeon. In entering the ministry of the Church he realised a youthful ambition, deflected for a time to medicine by parental wishes. Canon Arnott, I believe, rigidly abstains from any exercise of his old craft of surgery, whether by way of advice or practice, and this appears to be the safe general rule of those who leave the profession. His busy life in a large parish with four churches has left him little time to keep up his old and still vivid pathological interests. But he gives me leave to tell you that while medicine has no direct value in his present field of work, the old scientific training, the long hours spent in microscopic work, the power of sympathy with suffering, the realisation of the inexhaustible study and experience needed for anything like dogmatism in the ways and by-ways of nature, the humility necessary before the baffling problems of life and disease and death—all this is of incalculable value in his present profession. He speaks, too, of the knowledge of men and affairs which medicine gives, and of the intimate acquaintance with the seamy side of life to be gained perhaps better in a hospital surgical out-patient practice than anywhere else. Such is his personal estimate of medicine as a liberal education.

Keats and Goldsmith.

Of those who have forsaken medicine for poetry the most distinguished is perhaps the poet Keats, who was a qualified medical man and a Licentiate of the Society of Apothecaries. No trace of his medical knowledge is visible in the poems, but that medicine had important lessons for him may be judged from a comparison of the two following quotations: "My last operation was the opening of a man's temporal artery. I did it with the utmost nicety, but, reflecting on what passed through my head at the time, my dexterity seemed a miracle, and I never took up the lancet again." The second quotation refers to his poem "Endymion." "Had I been nervous about it being a perfect piece, and with that view asked advice, and trembled over every page, it would not have been written, for it is not in my nature to fumble." There speaks the surgeon, trained by his profession to the initiative which is so difficult for a man of poetic temperament. It is quite possible that but for his medical training Keats's vigorous self-criticism would have overcome him, and that his poems would never have been written.

After ineffectual attempts to qualify in divinity and in law, Oliver Goldsmith obtained a mysterious medical degree in the University of Padua during the course of his wanderings through Europe. Owing to the death of his benevolent uncle at this juncture he was thrown upon his own resources. With the aid of his flute he wandered homeward through France, and reaching London, he commenced medical practice in Bankside, Southwark, a locality once the site of Shakespeare's theatre, which is now given up to gigantic warehouses. Here he was seen by a Scotch acquaintance in the tarnished finery of a second-hand suit of green and gold, with a shirt and neckcloth of a fortnight's wear. Later he appeared in a full-trimmed suit of rusty black velvet with a patch upon the left breast which he adroitly covered with his hat during his professional visits, resisting politely but firmly courteous invitations to put down his hat. Practice was slow in coming, and Goldsmith decided to try for a medical appointment in the East India Company's service, at one of their factories on the Coromandel coast. Wealth beyond the dreams of avarice seemed within his grasp, for the salary was £100 per annum with private practice, but his utmost efforts at hack literary work failed to raise the sum required for his outfit, and the fair prospect vanished. Shortly after, in 1758, he presented himself at the College of Surgeons for examination as a surgeon's mate. Though the outer man was well furnished with a brave suit of clothes made for the occasion and to be paid for with four magazine articles, the examiners rejected him. He accepted their verdict as final and abandoned medicine. It seems, indeed, improbable that Goldsmith ever possessed more than a mere smattering of medical knowledge, and this is borne out by his pathetically careful attempts to dress for the part he was so ill-fitted to play. The fate of his examination suit of clothes well illustrates his delightful character. Four days after the examination he pawned it at his landlady's entreaty to deliver her husband from a debtor's jail. The suit not being paid for, poor Goldsmith himself narrowly escaped arrest at the hands of the irate tailor.

It is worthy of note that the present distinguished Poet Laureate has the Oxford medical degree and is a Fellow of the College. Mr. Bridges has educated himself for his high calling with a persistence worthy of Milton. After leaving Oxford and spending some years in travel, he set to work to supply the defects of a classical training, and having decided that medicine offered the most direct way of getting scientific education (a conclusion which I commend to your particular attention), he entered at St. Bartholomew's Hospital, where he became casualty physician. He was also physician at the Children's Hospital and at the old Great Northern Hospital. It is not difficult to see how his poetry must have gained in directness and humanity from his years of service to the London poor, which balanced and harmonised the complex elements of his intellectual training and prevented that atrophy on the volitional side which is the bane of a purely literary career.

Law and Politics.

The lawyer's training in dialectics and in the use of the spoken word gives him an overwhelming advantage in political warfare, quite apart from the profound knowledge of business and of human nature which legal experience brings. Thus in political life the law carries all before it, while the successes of medicine have been attained rather on the administrative and diplomatic sides than in the field of debate.

The careers of the late Lord Ilkeston, formerly Dr. Walter Foster, and of Dr. Jameson, lately Premier of the Dominion of South Africa, are too familiar to need more than a passing mention. Sir George Robertson, one of the heroes of the siege of Chitral, has to his credit a long and varied record of fighting and diplomacy among the wild tribes of the Indian frontier, where he proved himself an unrivalled manager of men. Few may know that his first ten years in India were spent in the Indian Medical Service.

Among doctor-politicians must also be reckoned Dr. George Ernest Morrison, who is an M.D. of Edinburgh University. Before the age of 21 he crossed Australia on foot from north to south. His subsequent travels carried him to the most inaccessible parts of China, and on one occasion he rode from Central China to Russian Turkestan, 3750 miles, in 175 days. Present at the siege of Peking, where he won fame as the omniscient *Times* correspondent, he is now the official political adviser of the President of the Chinese Republic, a post which at present would appear to be no sinecure. His name naturally recalls that of Dr. Sun Yat Sen, the first student of the English medical school established at Hong-Kong by Mr. Cantlie, and the organiser of the movement which led to the downfall of the Manchus. Whatever be thought of the political wisdom of his stupendous achievement, his disinterested patriotism seems beyond question.

Among distinguished lawyers recruited from the ranks of medicine must be mentioned the Right Hon. Sir Robert Finlay, Member of Parliament for Edinburgh and St. Andrews Universities, and a former Lord Rector of his own University of Edinburgh. The son of an Edinburgh physician, he graduated in medicine at Edinburgh, and was then called to the Bar. His brilliant subsequent career as Solicitor and Attorney General proves, at any rate, that a medical education offers no insuperable obstacle to subsequent legal success.

Art.

The late Sir Seymour Haden, founder and President of the Royal Society of Painter Etchers, the leader, along with Whistler, of the revival of etching in England, and one of the greatest exponents of the art, was a surgeon, and no mere dilettante one, for he studied not only in London but in Paris and Grenoble, had obtained the Fellowship of the College of Surgeons, and practised as a surgeon until the age of 52. He considered etching rather as a recreation than as the serious business of his life, so that his etched plates number only about 200 in all. Perhaps he gave too much of his life to medicine. If his art had been the single passion of his life he might have been the English Rembrandt. But he had that sanity and love for a balanced life which has often character[illegible] he refused to become the sla[illegible] struggle and the same victory [illegible] Robert Browning, who managed to become a poet, and a great one, without ceasing to be a man of the world.

Mr. Henry Tonks, assistant professor at the Slade School of Fine Art, is another instance of the doctor turned artist. Many generations of students have felt for him the affection not unmingled with wholesome dread which Sir Henry Morris used to inspire here. Deeply interested in his work and his students he will permit no slack worship at the shrine of Art. Mr. Tonks has sent me a delightfully frank letter in which he says:—

[illegible] to answer your letter in a satisfactory [illegible] deal.

Mr. Tonks goes on to say that a disadvantage of medicine is that it has become so vast that a young man has to leave much unlearnt and even unthought of. Here I would dissent from him, for it is one of the greatest advantages of medicine that, like a sea training, it brings a man up against the mighty forces and the vast complexity of nature, and teaches him his limitations. This, indeed, Mr. Tonks implicitly admits when he adds: "I think the reason why some professors are bores and prudes is that they have had so little time to see the relation of their subject to anything else."

You will all admit that no actor on our stage can give advice to youth in difficulties with such suave yet overwhelming authority as Sir Charles Wyndham. His celebrated "It won't work" speech in the last act of *The Liars* is perhaps the best instance that can be quoted. It is the physician in him coming out, for Sir Charles, now an acknowledged head of the dramatic profession, is a qualified medical man, and doubtless one of the lost leaders of medicine.

Science and Literature.

Sir Joseph Hooker, the director of Kew Gardens for 20 years, and a former president of the Royal Society, who died as recently as 1911 at the advanced age of 94 years, was perhaps the last survivor of the great Victorian men of science. Like Huxley he began his career as a naval surgeon, and obtained his chance of scientific distinction as surgeon to an exploring expedition, the chance which some of us who stay at home seek at the end of a microscope, and [illegible] count themselves the kings of [illegible] from the Ross expedi- [illegible] acted as surgeon and naturalist, he seems to have experienced a violent and very natural revulsion of feeling, for we find him next among the luxuriant vegetation of India, basking in the blaze of rhododendrons. He had found his vocation. His great claim to distinction is that by his studies on the distribution of plant life he produced what amounts to a botanical map of the world; and it was medicine which introduced him to botany.

Your familiarity with Huxley's career absolves me from speaking of it in detail. Like the career of Hooker, it illustrates a great practical advantage of a medical training, to which I may here call attention. It is a key, albeit not a golden one, which unlocks the pageant of the world. In this respect it has no rival among the pacific professions. The law and even the church must stay at home when the poles have to be reached or an unknown territory crossed. But the doctor cannot be spared. The steamship companies will show him the gorgeous East and provide him with pocket money if he cares to take a voyage as ship's surgeon. There are few parts of the world to which the exercise of his profession will not take him if he so desires. His training in observation has prepared him to use his privileges; witness the careers of Hooker and Huxley. A man can hardly have a medical training without being able to say with one of Mr. Morley Roberts's characters: "I sees what I looks at," and, as explorers, doctors have been very successful. I need only recall to your memories the careers of Livingstone and Mungo Park.

Among those who have left medicine, though his heart is still with us, we must perhaps count our former colleague, Mr. Stephen Paget. Gifted with too complex an intellectual outlook, and torn between the claims of science and of literature, Mr. Paget has solved the problem of serving two masters in a unique way by becoming the literary protagonist of science. His work as secretary of the Research Defence Society is of incalculable value to the cause of science in this country.

[illegible]

The Educational Advantages of Medicine.

You will see from the examples I have given you that the renegades of medicine include an unduly large proportion of men who have subsequently reached eminence in other spheres of activity. Now the class is not a large one, for few men leave our profession, a fact dependent on its inherent interest and attraction. It is then a fair inference that the study of medicine provides a liberal education, one which so develops the individual that it fits him for any of the varied calls life in its other departments may make upon him. The renegade doctor is likely to be found near the top of his particular tree. You will probably accuse me of unduly depreciating the accepted forms of liberal education, and it is perfectly true that science is no substitute for a literary and linguistic training. I maintain only that it is their necessary complement. Attempts to make science the main ingredient of school education are predestined to failure. They fly in the face of the great biological generalisation that the development of the individual is an epitome of the development of the race. The human embryo begins as a unicellular organism and passes through a stage in which it possesses gill-slits like a fish before it assumes the final mammalian form. In accordance with this principle, which seems to me to supply the key of some educational difficulties, the attention of the boy is rightly directed to the preoccupations of earlier civilisations, to language, classics, and history. A scientific man, if denied the power of expression which only a literary training can give, is deprived of most of his power to influence his fellows. But given the literary foundation, an acquaintance with natural science, the most recent achievement of the race, is necessary to complete the edifice. This training will naturally fall in the university or post university stage of education.

For the general purposes of life I believe, with Mr. Bridges, that medicine, which blends with and merges into pure science in every direction, is the best way of getting a broad general acquaintance with scientific thought. As compared with pure science it has the *advantage that it does* not exclude the human interest, and that it breaks down that morbid dread of plebeian contact, that *want of recognition* of the dignity of service, which is not infrequently seen in the educated Englishman. Goethe, who studied *medicine* and acknowledged its charm, says: "My *disgust* at the patients gradually decreased as I *learned to* forget their physical condition in the ideas *suggested by* it, which rendered possible the restoration of human form and human life." The personal service *which* the medical student cheerfully gives to the more unfortunate of his fellow citizens, the intimate contact he *makes* with their miseries and heroisms, virtues and vices, must tend to broaden his outlook on life. He who washes the *beggar's feet* may find his own hands whiter than before.

Time forbids me to discuss fully the educational advantages of medicine, though much might be said. As a *training* in resourcefulness and presence of *mind it is as good* as the fighting services, for its opportunities are daily ones.

In this connexion I may remind you of the repeated testimony borne by our national hero, the late Captain Scott, to the practical wisdom of his medical comrade, Dr. E. A. Wilson, to whose judgment one and all appealed in matters small and great. Like the middy on the torpedo boat, the medical man gets his responsibilities early. The house surgeon just qualified must be prepared at any moment to perform tracheotomy, a delicate operation in which death will call an immediate checkmate to any false move. And he must do it publicly before the critical eyes of his fellow residents. The fact that he usually does it so well shows the excellence of his previous training.

The Value of Scientific Knowledge to the State.

I have no wish to institute comparisons between medical training and the established forms of liberal *education*. As Sir Oliver Lodge said recently: "Let us *not fall* into the old mistake of thinking that ours is the only way of exploring the multifarious depths of the universe, and that all others are worthless and mistaken. The universe is a larger thing than we have any conception of, and no one method of search will exhaust its treasures."

But for this very reason some of those fortunate people who have leisure for full self-development should *complete* it through science. In our national leaders, collectively if not individually, we have the right to expect that combination of literary and scientific training which was the source of Goethe's strength. Only thus can the complexity of the universe be properly reflected in their intellectual equipment. In my opinion that is not at present the case. To take a crucial instance, I have not been able to ascertain that more than one member of the present or the last Cabinet has received an education in natural science. It is not sufficient that the man of science should be at hand to be consulted; the scientific habit of mind must be directly represented in the national councils. Let me try to illustrate the evils attending the present state of things.

Last June Mr. Balfour, whose sympathies with science we gratefully acknowledge, opened some new buildings of the National Physical Laboratory at Teddington, the institution which tests and standardises optical and other instruments and undertakes *physical* researches of public interest. Among a number of subjects it has taken up this year one alone, the testing of roads and road surfaces, touches the expenditure of *millions of public money* annually and affects the comfort and well-being of the whole nation. Is it not extraordinary that this institution—national in the fullest sense—should be dependent on private generosity for necessary extensions to its buildings? Yet such is the fact. The spectacle is as grotesque as that of a millionaire inviting subscriptions among his friends to provide his steam yacht with a compass. I present this idea to the Gilbert of the future, and suggest "We can't afford a compass, so we'll go to sea without," as the refrain of the final chorus. In sober fact, the phrase represents not inaccurately the present attitude of the nation towards science.

Lord Beaconsfield's *purchase* of the Suez Canal shares for the nation is now hailed as a stroke of financial genius. The statesman who demanded of Parliament half a similar sum for the endowment of the University of London with a department for the investigation of tropical disease would make a better investment for his country even from a monetary point af view.

Another of our statesmen, Mr. Austen Chamberlain, continuing a work begun by his distinguished father, is attempting with great personal devotion the task of raising a fund for the London School of Tropical Medicine, an institution on which, believe me, the future of the British Empire largely hangs. But while we see our statesmen supporting science by their sympathy and private efforts, we shall not find them adequately exerting their authority in Parliament in the same cause until some of them receive a scientific education. The safety and progress of the State is as much bound up with national progress in scientific knowledge as in the maintenance of an adequate navy.

You may think that I use the language of exaggeration, but when you reflect that the Panama Canal has *only* been rendered possible by laboratory investigations dealing with an obscure mosquito, suggested in their turn by Sir Ronald Ross's investigations on the mosquito which carries malaria, you will agree that I have not overstated the case. Here is a little piece of scientific knowledge which could be written on a visiting card: "The stegomyia mosquito is the vehicle which carries the organism of yellow fever from man to man." Without this knowledge the French attempt to cut the Canal ended in the waste of many thousands of lives and £50,000,000. Knowing this secret the American engineers and doctors have succeeded. It may ultimately be realised that the expenditure of money in scientific research and in the support of institutions for the advance of knowledge is *not the* mere luxury of a rich nation, but one of the surest means of increasing the national wealth as well as the national happiness.

It is interesting to note that in the opinion of Pasteur, the great French scientist, the downfall of France in the war of 1870 was due to the national neglect of science. Under the first Napoleon science had flourished. For his expedition to Egypt he had organised a special staff of scientific men to accompany him. He had such a respect for the discoverer of vaccination that he never refused a request from Jenner for the release of an English prisoner.

What happened later in France may be expressed in Pasteur's words: "A victim to her political instability France has done nothing to keep up, *to propagate and to* develop the progress of science ...... ; she has lived *on* her past, thinking herself great by the scientific discoveries to which she owed her material prosperity, but *not perceiving* that she was imprudently allowing the sources of those discoveries to run dry. ...... While Germany was multiplying her universities, ... creating vast laboratories amply supplied with the most perfect instruments, France, enervated by revolutions, ever vainly seeking the best form of government, was giving but careless attention to her establishments for higher education."

After the war it was to science that Pasteur mainly looked for the regeneration of France. His opinions might be dismissed as an expanded version of the cobbler's dictum that there is nothing like leather. They may appear as high-sounding generalities, possibly *containing a portion of* truth, but mainly expressive of a natural loyalty to his scientific colleagues, or of a narrow-minded enthusiasm. They might even be ascribed to veiled [illegible] who never dealt in vague [illegible] proving their truth. And i [illegible] apart from the human lives they have saved, the material benefits his researches brought to the brewing, farming, and silkworm industries of France sufficed to pay the vast war indemnity which the victors exacted.

You will see now why I believe that one of the most *urgent needs of the day is the presence among our leaders*, who at present receive almost exclusively a classical, a literary, or a legal education, of a larger number of men who have had a scientific training. To those ambitious young men who aspire to mould the destinies of their country I would say: Leave the past when you have attained your degree in arts and come where knowledge is alive and [illegible] strenuous five years [illegible] the mental discipline [illegible] In your subsequent career of politics or public service of whatever kind you will find *that the time has been well spent*, and that the skill you have acquired in applying precise knowledge of many kinds to the service of humanity finds many applications in the wider spheres to which you may be subsequently called.

Introductory Address

ON

THE WORK OF THE MEDICAL PROFESSION IN INDIA.

Delivered at the Opening of the Winter Session of the Medical School of St. Mary's Hospital on Oct. 1st, 1913,

BY SIR JOHN P. HEWETT, G.C.S.I.,

LIEUTENANT-GOVERNOR OF THE UNITED PROVINCES OF AGRA AND OUDH.

GENTLEMEN,—The invitation from Sir John Broadbent to preside at this gathering was as agreeable to me as it was unexpected. It is a great honour to be given the opportunity of expressing in public my admiration for the accomplishments and devotion of the profession which the students at St. Mary's Hospital Medical School have chosen to follow. It is one of the noblest that a man can undertake, and perhaps the only one that will command the same regard and esteem to the end of time.

When asked to give an address on this occasion I found [illegible] *has been effected in India by medical men, and to endeavour* to convey some idea of the enormous field that still lies open to them there.

VITAL STATISTICS OF INDIA.

The registration of births and deaths has only been attempted in India for about the last 40 years, and, as most of the reporting agency is illiterate, the causes of death are very incorrectly recorded though the number of deaths is reported with fair accuracy. Specific fevers, such as malaria, small-pox, and influenza; abdominal diseases, such as cholera, dysentery, and diarrhœa; and lung diseases, *such as tuberculosis, pneumonia*, and bronchitis, are those which cause the greatest havoc among the Indian population. You will readily understand how difficult it is to ensure even approximate accuracy in reports of the cause of death. Moreover, nearly 71 millions of the population of 325 millions live in the Native States to which the rules and regulations in force in British India do not apply. My remarks therefore refer only to the 254 millions resident in British India. The annual death-roll in British India amounts to about 7½ millions, of which about 40 per cent. [illegible] ordinary that the country should, in spite of them, be, so far as the increase of its population is concerned, in a condition which would be *envied by some European nations*. The average death-rate during the past 10 years has been 34 per 1000, or, if deaths from plague are eliminated, 31·5 per 1000. In the same period the birth-rate has averaged slightly over 38 per 1000, with the result that the births reported have exceeded the deaths by about a million in each year of the decade. Though it is indisputable that the public health has improved in many respects in the past half-century, the data available are not adequate to enable us to gauge the extent and manner of the improvement. And whatever the improve*ment already effected, the main reflection about these figures* must be that if we describe the problem which still confronts the medical profession in India in the direction of reducing infantile mortality, malaria, and other fevers, and abdominal and lung diseases as being one of portentous magnitude we shall not be using an expression of exaggeration.

IMPROVED HEALTH IN ARMY AND IN JAIL POPULATION.

When we turn to the classes to whose well-being medical science has been specially directed, and regarding whose condition accurate statistics over a lengthy period are available, the results are most encouraging. These classes are the army and the jail population.

The mortality among British troops serving in India was 55 per 1000 between 1770 and 1800, 84 per 1000 between 1801 and 1830, and 58 per 1000 between 1831 and 1856. The Royal Commission of 1863 took a death-rate of 20 per 1000 as a possible rate under improved sanitary conditions. In the ten years ending in 1878 the death-rate had been reduced to 19·8. It has since 1900 averaged 9·5, and in 1911 was 4·89. Making all allowance for the fact that in the earlier years of our occupation the mortality on service was high these results are extraordinarily good. The mortality among the wives of soldiers has been reduced to one-third of what it formerly was, and that among their children to one-half. The diseases mainly responsible for the high death-rate among the British troops in the past were enteric fever, abscess of the liver, and cholera and other epidemics. The death-rate among the native troops, among whom pneumonia is the most fatal disease, was between 1871 and 1880 over 20 per 1000, and in the last six years of last century 11 7 per 1000. In 1911 it had fallen to 4·48 per 1000, or if deaths among men on sick leave or furlough are included to 6·78. *The medical officers in* charge of our army in India have indeed achieved a record of which they and all the members of their profession may well be proud.

The results among the jail population have also been very satisfactory Here the most common causes of death are dysentery, pneumonia, and tuberculosis of the lung. The number of deaths from epidemics is very small; fewer men in j[illegible] the native army. F[illegible] ged 71 per 1000; i[illegible] s reduced to 49; in the *last five years of last century* it was 30. *Since* 1900 it has averaged 20·5, and in 1911 was between 18 and 19. I may, perhaps, mention an instance of the beneficial effect of the supervision of a jail by a medical officer which came [illegible] at one time the practice [illegible] ler superintendents who [illegible] work in the jail being undertaken by a subordinate native medical officer, subject to the superintendence of the health officer of the district who had many other duties and was only expected to pay one visit daily. The death-rate in this jail for some years had been about 50 per 1000, and it had even gone considerably over 60. After studying the condition and statistics of the jail it seemed to me that the medical supervision was not adequate. I therefore determined to appoint a medical officer to the sole charge of the jail. The most remarkable result ensued: within one year the mortality was reduced to just over 19 per 1000.

Towards the results in cantonments and jails sanitary improvements of all kinds, a purer water-supply, and a better system of drainage have contributed in no small degree. But there are enormous areas, including most of the villages in India, in which there are no sanitary arrangements whatever worthy of the name, in which the water-supply is impure, and in which there is no system of drainage at all. And there is scarcely any place, whether city, cantonment, or village, in which there are not defects in hygiene so glaring as to shock the sanitary reformer. The Government of India are doing all that lies in their power to remedy these defects. They have given in recent years enormous sums of money towards sanitary improvements, and have neglected no opportunity of encouraging the people to pay more attention to hygiene. But progress is necessarily slow, and improvement must be gradual if it is to be permanent.

Benefits derived from Experiments on Animals.

I have had the honour to be associated as an administrator with medical officers in combating certain diseases in India, and the experience gained in this work has afforded the clearest proof that, but for the knowledge acquired by means of experiments on animals, the prevention and treatment of some of the most grievous afflictions of the human race in India would have been far less successful than they have been. Some people affect to consider that medical men are prejudiced in their defence of vivisection and other experiments on animals. This insult to the members of a most honourable profession tempts me to say a few words on the subject. I have no claim to speak with any approach to the authority of Lord Cromer, whose introduction to Mr. Stephen Paget's excellent book "For and Against Experiments on Animals" is a model alike of style and judicial reasoning. But I can at least claim to have had some opportunity of estimating at first hand the value of certain methods of treatment which depend on experiments on animals. And I can point to the fact that, when associated with my friend Sir Almroth Wright on the Indian Plague Commission, I felt bound to differ from him on some very important matters discussed in our report, such, for instance, as compulsory corpse inspection in plague epidemics, as proof that prejudice has played no part in the opinion that I have formed as to the results of those methods.

Small-pox and Vaccination.

I would first refer to the statistics regarding small-pox. There is a Hindu goddess of small-pox called Sitla, in whose honour religious fairs are held and largely attended. The disease prevails to an extent unknown in modern Europe, and its evil effects are aggravated by the fact that an enormous number of those who contract it never receive any medical treatment during the attack. It was not till about 1850 that a serious attempt was made to introduce vaccination into India. In that year some 350,000 persons were vaccinated; the number annually vaccinated in these days approaches 10 millions. The death-rate from small-pox, which 30 years ago was nearly 1 per 1000, has steadily declined until it is now only about one-third of that amount. Moreover, it has been noticed that the number of pock-marked young people of both sexes is far smaller in the present day than was formerly the case, and that, while the proportion of the wholly or partially blind among the young used to be highest where small-pox was most prevalent, it has decreased in general accordance with the territorial spread of vaccination. I submit that no fair-minded person can avoid the conclusion that these results have been due to vaccination. In the face of the clear proofs of its efficacy it is surely calamitous that the opponents of vaccination in England should have set themselves to make the people of India hostile to a process which has brought them so much benefit.

Inoculation against Plague.

I have already referred to the terrible mortality from plague in the last 15 years. It has long since been recognised that, except in extraordinary circumstances, compulsion is impossible, and the great obstacle with which the Government has been confronted is the difficulty of convincing the people of the utility of particular methods of prevention or cure. It is not easy to appreciate the mental attitude of people who, without having made a serious study of the facts and figures pertinent to the question, have increased the difficulties of those doing their best to contend with this terrible scourge by asserting that the vaccine discovered by M. Haffkine has encouraged the spread of the plague in India. There have, of course, been instances in which evil results have been caused by particular doses having been unfit for use, or by the carelessness of individuals injecting the vaccine, but such cases have been rare, and the use of the vaccine has been, speaking generally, of enormous benefit. The conclusion at which we members of the Plague Commission unanimously arrived in 1899 was that "inoculation with Haffkine's prophylactic vaccine sensibly diminishes the incidence of plague attacks on the inoculated population, though the protection which it affords is not absolute; that it also diminishes the fatality of attacks; that its protective effect does not appear within the first few days after the inoculation, and that the protection lasts certainly for some weeks, possibly for some months."

Since this conclusion was formulated I have had, as the head of the Government of two provinces in succession, one with a population of 47,000,000 and one with a population of 14,000,000, to deal continuously with outbreaks of plague. The whole of my experience gained in this interval has confirmed the conclusion of the Plague Commission, and the statistics of the many epidemics in which inoculation has been practised under my own eyes go to prove that the use of Haffkine's vaccine has been of the greatest service in protecting people from plague. I could quote many cases, but I will content myself with one which has always impressed itself very much on my mind. A Parsi friend of mine, Sir Bezonjee Dadabhoy, the manager of the Empress Mills at Nagpur, in which city some years ago a serious epidemic resulting in the death of over 7000 people occurred, endeavoured to induce the whole of the operatives of the mills to be inoculated. The total number on the muster rolls was between 6000 and 7000, and the daily attendance between 4500 and 5500. The number of mill hands inoculated was 5046 Among the comparatively small number of uninoculated there were 118 deaths, while among the inoculated there were only 9 fatal cases, 6 of which were the result of an attack within 10 days of inoculation.

This is a report from one whose only interest was to benefit the operatives in his employ, and the facts narrated in it prove conclusively that by inducing them to be inoculated he secured protection for them during the epidemic.

Antityphoid Vaccination.

Turning to enteric fever, the first thing that claims attention is that it is much more prevalent among Europeans than among Indians. For many years it was chief among the fatal diseases prevalent in the British army in India. In the last five years of the last century 43 out of every 100 deaths among British soldiers were due to enteric fever. The greatest liability to suffer was between the ages of 20 and 25 and during the first year of service in India, the liability of men to contract it in the first year of service being at least twice as great as in any other period. At the end of last century the possibility of life would have been as good for the European troops in India as for males of the same age in England had it not been for the prevalence of enteric fever.

The chief task then before the medical officers employed with British troops was the reduction of the liability of the British soldier to enteric fever. In 1898, only 15 years ago, the mortality from this cause was over 10 per 1000; among the native troops it was the same time something between 0·01 and 0·02 per 1000. The use of Sir Almroth Wright's antityphoid vaccine was attempted about this time in a spasmodic way, but it was not till 1903 that this plan of fighting enteric fever became general. In that year 295 deaths were caused by enteric fever, and the mortality caused by it was over 4 per 1000. Since then the death-rate declined, till in 1910 it was 0·63, and in 1911, the number of deaths being 24, only 0·33. In the latter year there were 61,822 men protected by vaccination and 9552 not protected. Among every 1000 of the non-protected men there were 6·7 cases and 1·15 deaths, while among every 1000 of the protected there were 1·7 cases and 0·17 death. We must not, indeed, forget that a great deal has been done in the direction of isolating convalescents and bacilli-carriers, but these figures, like those regarding men in the army in France and America, conclusively prove the beneficial results of antityphoid inoculation.

A striking instance came under my observation at a military station where outbreaks of enteric fever were of very frequent occurrence The introduction of antityphoid vaccination resulted at once in a large diminution in the number of cases and deaths In 1912 out of 693 men serving in four batteries of artillery stationed there 687 were protected by inoculation There were in that year two cases among the six unprotected men, but only one case among the 687 who had been protected The officer commanding a battery serving there wrote to me recently that all of his men had been inoculated for some years He added, "I have never lost a man since, nor have I had a case of enteric that I can remember till this year When I remember the number we used to lose in a battery each year I am astounded at Sir Almroth Wright's genius!" I can supplement this with my 35 years' experience that from the time when I first went to India till the use of Sir Almroth Wright's vaccine became established the cemeteries in the cantonments of the United Provinces were strewn with the graves of young men who had gone to serve their country in India only to be carried off by enteric fever within a year or two of their leaving home Now that the death rate even in a newly arrived regiment has fallen to what it might be expected to be in England the conditions have completely changed

Snake bite and Hydrophobia

It remains for me to refer to two risks to life in India from which people in Great Britain are entirely exempt Some 22,000 deaths are annually reported in India as having been caused by snake bite Admitting that this figure includes a number of deaths due to other causes there is still a large residuum really due to snake bite Antivenins which will, if promptly administered, prevent the bite of the cobra and Russell's viper respectively—two of the most poisonous snakes met with in India—from being fatal have been discovered by means of experiments on animals, and it is to be hoped that further discoveries may result in making similar treatment of the bites of other poisonous snakes feasible

An even more terrible scourge than snake bite is hydrophobia Inhabitants of Great Britain are, owing to the foresight and firmness of Mr Walter Long, saved from all apprehension on this score It is vain to hope that the disease can ever be exterminated in India, where pariah dogs, jackals, and wolves alike can convey rabies Till the end of the last century a patient bitten by a mad animal had no remedy in India Only the well to do could afford a journey to the Pasteur Institute in Paris, and, owing to the length of the voyage, this might often be undertaken in vain The poorer classes could only suffer and die in silence In 1900 a Pasteur Institute was established at Kasauli The number of cases received at the institute between 1900 and 1911 was 13 540, the patients being of every rank of life There were 225 deaths in cases in which the treatment could not be applied in time, and 81 failures in which the patient died more than 15 days after the completion of the course But the treatment as a whole shows a splendid result The long distances that have to be travelled in India made it evident that one institute was inadequate One most pathetic case occurred of a young English lady who, while expecting her first child, was bitten by a mad dog during the hot weather in the South of India She had to undertake a terribly hot railway journey of nearly a week Her case proved to be too advanced for hope, and she died in terrible agony A second institution has since been established in the South of India and a third is to be established in Burma When this arrangement has been completed some institute will be fairly accessible from any point in the territories under the Government of India, and provision will have been made to prevent an enormous amount of terrible misery, though with the number of habitations scattered over the country it will be impossible to prevent many cases from failing to come under treatment

CLOSING REMARKS

What I have attempted to tell you to day will, I am sure, satisfy you that experience in India, as elsewhere, proves conclusively that operations on animals have afforded untold benefits to the human race Performed with the utmost care by skilled surgeons, they are rendered almost painless through the use of anæsthetics, and are followed by a drug-softened death As instances of cruelty to our dumb friends, how can they possibly be compared to the limitless sufferings imposed on beasts of burden and other animals, on whose aid mankind depends, in India and many foreign countries? One experiences every day in an Indian city horrors in the treatment of animals, inconceivable to the stay-at-home inhabitant of these isles accustomed only to the pampered pets and well fed cattle of himself and his neighbours What a field for the tactful energy of animal lovers there is in that vast country, where pity rarely impels the passer by to put a wounded and stricken animal out of pain instead of leaving it to die a lingering death; where beasts of burden of all kinds are systematically over loaded and regularly worked when they ought to be in the care of the veterinary surgeon, and where even the cow, the sacred animal of the Hindus, is confined in evil smelling and ill-ventilated hovels, and often milked by the horrible phuka system which causes it terrible suffering At present only one institution, enfeebled through lack of funds, makes spasmodic efforts to instil into the starved brains of owners and drivers of beasts some dim recognition of the fact that consideration shown to their cattle is likely to reflect substantial gain on themselves For lovers of animal life, for those whose earnest wish it is to save the beasts of the field from unnecessary cruelty, and to ensure for them the minimum of harshness and pain involved in their use in the service of man, there is in India a splendid field for benevolent work which will, like mercy, be twice blessed in bringing relief to the animals which now suffer and honour to those who undertake it Such cases, too, as that of the creature Baker—he doesn't deserve to be called a man—who was recently convicted of sending on a long railway journey a poor little Aberdeen terrier which had been mercilessly pushed into a box utterly inadequate for its size, and with ventilation insufficient for a canary, show that there is still much nearer home to occupy the Royal Society for the Prevention of Cruelty to Animals, whose vigilance we all admire But the last people in the world who deserve to be attacked, on the ground that they are cruel or even unsympathetic towards animals, are those devoted seekers after benefit to the human race, who are in this country, in pursuance of the objects of the Research Defence Society, conducting experiments on animals subject to strict rules and regulations and imbued with the righteous desire to cause them the least possible misery and pain

TWO CASES OF AURICULAR FLUTTER.

BY JOHN HAY, M.D. VICT., M.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN, ROYAL INFIRMARY, LIVERPOOL.

IN 1908 Hertz and Goodhart[1] published a case in which there was a remarkable discrepancy between the frequency of the auricles and the ventricles. The auricles contracted at an average rate of 220 beats per minute, the ventricles infrequently, varying from 75 to 156 beats per minute. Later, in 1910, Jolly and Ritchie,[2] in reporting a somewhat similar case, applied the term "auricular flutter" to this condition, and this name has been accepted. Since then numerous cases have been reported; the most important and complete account is to be found in a paper by Lewis,[3] in which he has collected all the cases published up to that date. Since the publication of Lewis's paper, Ritchie[4] and Hume[5] have recorded further cases.

Such cases are of extreme interest and importance, but as the whole ground has recently been carefully covered by these writers, I will content myself with giving the history and tracings of two patients suffering from auricular flutter whom I have had under observation. They present certain points of interest in diagnosis, prognosis, and treatment.

CASE 1.—The patient, aged 40, was admitted to the Stanley Hospital, Liverpool, under my care on May 29th, 1906, complaining of shortness of breath, swelling of the feet and legs, and palpitation on exertion. Later he was a patient in the Liverpool Royal Infirmary in Dr. T. R. Bradshaw's ward, through whose kindness I had the opportunity of continuing my observations.

Past history.—The patient had suffered from the usual children's ailments, and had had small-pox at the age of 21 and malaria in 1900. He never suffered from rheumatism or growing pains. He had always been a heavy smoker, and until 1904 had taken alcohol in excess. He first began to notice difficulty in breathing in the early part of 1906. In April of the same year he became very œdematous and required hospital treatment. He was markedly cyanosed when admitted to the Stanley Hospital. The earliest note as to his heart was made on May 30th, 1906. The heart's action was irregular, rate 76, and the blood pressure was raised. The cardiac dulness extended 1¾ inches to the right and 5½ inches to the left of the middle line. The apex beat was not distinct, but there was a diffuse heaving in the fifth and sixth spaces in the nipple line. On listening over this diffuse impulse a distinct systolic murmur was heard, followed by a loud thumping second sound. There was a troublesome cough and evidence of fluid at the right base. Urine: specific gravity 1012, acid, no sugar, trace of albumin.

The interesting features in this case can best be followed by examining the graphic records.

Fig. 1, taken on June 11th, 1906, shows remarkably well the alternating character of the radial pulse. This was very noticeable at that time and was the chief element in the irregularity. The jugular tracing is poor, but in the light of later records we know that the small waves, *a*, are due to auricular systoles; they represent a frequency of about 240 per minute. *c* denotes movements of the lever due to the pulse in the carotid artery.

On Sept. 30th, 1907, the pulse was regular—about 70 per minute with occasional intermissions. On carefully analysing the tracing seen on Fig. 2 we find a 3 to 1 ratio. The auricles are beating 270 times per minute and the ventricles 90. The radial pulse is regular and a little more frequent than normal, and it would obviously be impossible from an ordinary examination of the patient to surmise that the auricles were beating with such great frequency. The record Fig. 2 shows an intermission; there is a long pause interrupting the regular contractions of the ventricles. There is no corresponding pause in the jugular tracing, for the waves due to auricular systole continue without variation. It was portions of the tracing such as this which led me to recognise that the cardiac condition was unusual.

Five months later a different phase was noted, as shown in Fig. 3. In this tracing the radial pulse is absolutely regular, and its rate is 60 per minute, apparently a normal action, and yet the man was not well—the reserve power of his heart was defective. In this tracing, taken on March 19th, 1908, we find the auricles acting more quietly at 240 per minute, and the ventricles responding to every fourth auricular systole, a 4 to 1 ratio. He is now under the influence of squills; this member of the digitalis group has depressed the conducting power of the junctional tissues and increased the degree of heart block, transforming the 3 to 1 to a 4 to 1 ratio. On April 9th, 1908, 20 days after the previous record showing a 4 to 1 ratio, a change was noticed: the pulse had become quite irregular and disorderly in its rhythm. The tracing Fig. 4 was taken on this date, and reveals that the auricle is now fibrillating; the very small and extremely rapid movements of the auricle are not recorded in the jugular tracing. Fibrillation of the auricle has replaced the auricular flutter. The squills has done its work.

He left hospital very much improved, and shortly afterwards obtained regular work. I met him by chance in the beginning of November, 1912, and he reported himself in excellent condition. At my request he gave me an opportunity of examining him again, and I found the heart was contracting normally. The deep cardiac dulness extended 1 inch to the right and 4 inches to the left of the middle line. The thrust of the apex beat was best felt in the sixth space, and a faint systolic murmur was audible localised to the area of the apex beat. He had no difficulty while he kept to the flat, but hills and stairs proved a burden. Fig. 5 shows the type of jugular record at this date. Note the large bifid *a* wave followed by the small *c* or carotid wave, and that the *a.c.* interval is prolonged to 4/15ths of a second. There can be no doubt that under squills the fibrillation had given place to a normal action of the heart, accompanied by a great gain in reserve power. There is still crippling, but so long as the sequence of contraction is normal he can work and earn a living.

Summary.—We have records of a man of 46 extending over a period of about seven years, demonstrating the presence of auricular flutter with a 3 to 1 ratio and occasional irregular action of the heart. When first seen alternation of the radial pulse was pronounced; this disappeared entirely while under observation. Later a 4 to 1 ratio is observed. Then in 1908 under the influence of squills the auricular flutter changed to auricular fibrillation, which in its turn gave way to a normal sequence of contraction. The heart continues to contract normally, and the patient, much improved, is earning his living.

CASE 2.—The patient, a man aged 62, was first seen in consultation with Dr. J. C. M. Given on Oct. 1st, 1912.

Past history.—For 10 years the heart had been larger than normal and occasionally irregular in its action. For the last two and a half years he had noticed that exercise produced breathlessness. That summer there had been a great increase in the liability to dyspnœa, and once or twice when golfing he felt giddy and dazed. Sometimes he experienced a sensation of fluttering behind the sternum, which he described as if there were "a bird loose in his chest." His wife had noticed for some months that when he was asleep there was a rhythmical increase and decrease in the depth of his breathing.

He was a long, thin man, and when I first saw him he was lying comfortably in bed. His general appearance was healthy, there was no œdema, and his urine was normal. The heart was much enlarged, and there was considerable heaving of the præcordium and forcible apex beat. The deep cardiac dulness extended 2 in. to the right and 6 in. to the left of the middle line. A systolic murmur was heard over the apex beat, localised and not conducted into the axilla, and a faint diastolic murmur was audible down the sternum. The systolic blood pressure for the larger beats was 170 mm. Hg; the diastolic pressure as estimated with the phonendoscope was 80–90 mm. Hg. The pulse-rate varied and averaged about 84, irregular in time and force. On Oct. 8th records were taken (Fig. 6); the radial pulse was very infrequent and almost regular in the first tracing. The remarkable feature was the presence of extremely numerous waves in the jugular veins, due to the auricular systoles. These waves became more evident in the latter half of each

diastolic pause; they were masked in the earlier portion by the free movement of the lever caused by the large carotid pulse in the neck The auricles were beating 300 times per minute Other records showed that some of the ventricular systoles were unable to send a palpable pulse wave to the wrist

No further tracings were taken for a month, as he went to the South of England for a change He returned feeling very much the better for the rest At my suggestion while in London he saw Dr James Mackenzie, and electrocardiograms were taken by Dr Thomas Lewis In Fig 7 we have the electrocardiograms kindly taken by the latter The elevations marked *x* indicate systolic contractions of the auricles and the larger deflections represent contractions of the ventricles When this record was obtained the ratio was 3 to 1 The lower record in Fig 7 was taken almost immediately after the previous records Here we have a 4 to 1 ratio interpolated in a 3 to 1 series

On Nov 8th, shortly after his return, I obtained further tracings His radial pulse was regular, with a very occasional intermission He was much improved, the breathing was much easier, the cardiac reserve was greater, and he experienced no discomfort on easy walking Pulse 80 to 84 per minute Blood pressure 140 mm Hg systolic, 100 mm Hg diastolic A 3 to 1 ratio was present, the frequency of the auricle being 261, ventricles 87 (Fig 8) Occasionally a longer pause ensued, and instead of the ventricles responding to every third systole of the auricles the ratio is 6 to 1, followed by a 4 to 1, and then the 3 to 1 ratio is resumed Note in this tracing the significant alternation in the pulse It was decided to give digitalis in large doses, and he was accordingly ordered the B P tincture, 40 minims daily. On Nov 26th, after he had taken 290 minims, I took another tracing (See Fig 9) The ventricles were beating comparatively regularly while the record was being taken, but after walking about their frequency was increased and the rhythm became less regular

Note that the auricles are still contracting at the rate of 260 per minute, the ventricles about 31 per minute A condition of complete block has been induced by full dosing with digitalis The auricular waves *a* are excellently seen in the jugular pulse When the ventricles were contracting at this funereal pace the patient experienced an unpleasant sensation of tugging with each heart-beat The digitalis was continued until he had taken in all 360 minims; then as the ventricles continued to contract at 30 and there were no signs of the auricular flutter giving way to auricular fibrillation as the first step to the resumption of a normal rhythm, we stopped the continued administration of the digitalis, and since then have only allowed sufficient to act as a restraining influence and prevent undue frequency of the ventricles On Dec 1st, 1912 (when in bed), records showed the peculiar coupling of ventricular systoles which one sees so frequently in cases of Stokes Adams disease or auricular fibrillation under the influence of digitalis (Fig 10) The pulse rate was then very infrequent

It was of interest to note that at times the radial pulse showed a superficial resemblance to that of the disorderly rhythm of auricular fibrillation (Fig 11) Towards the end of January it was quite impossible to obtain any record of the jugular pulse Careful examination of the sphygmograms, using the method of spacing described by Lewis, at once reveals that these are the records from a patient in whom the auricles are in a condition of flutter For example, in Fig 11 the space *a* exactly coincides with the space *b*, and so on At the time these records were taken the patient was feeling much better and looked remarkably well He felt that his cardiac reserve was much improved The pulse varied considerably in frequency and regularity To a casual observer feeling it for the first time it would give the impression at one time of intermissions due to occasional extrasystoles, at another of the irregularity due to auricular fibrillation The blood pressure was 160 mm Hg systolic, and 100 mm Hg diastolic At this time he was taking 10 minims of the official tincture of digitalis each night, which amount was just sufficient to steady the action of the heart, but not enough to cause undue slowing of the ventricle such as was present on Nov 26th (Fig 9) It is of interest to note that the slight tendency to Cheyne Stokes respiration quite disappeared, and that there is now no evidence of alternation in the pulse, such as we see in the tracing taken on Nov 8th (Fig 8) In spite of the abnormal frequency of the auricular systole he feels well, transacts a certain amount of business three mornings a week, and enters into ordinary social life

Summary —A man aged 62 came under observation with a large heart and peculiar arrhythmia For 10 years the heart has been known to be increased in size, and occasionally irregular in its action The auricular rate was 300; the ventricular 50 to 60, and coupled A month later a 3 to 1 rhythm was present—auricular rate 261, ventricular rate 87 Cheyne Stokes respiration and alternation of the pulse were noted Large doses of digitalis produced a high grade of heart-block, but the auricular flutter persisted and is still present The general condition of the patient is much improved A small dose of digitalis daily is required to moderate the frequency of the ventricle

Note —On April 17th I took polygraph records These demonstrate that the "flutter" has ceased and that the heart is again acting normally with the exception of numerous extrasystoles originating in the auricle

Liverpool

HEMIPLEGIA FOLLOWING SYPHILIS,

WITH SPECIAL REFERENCE TO A CASE OF DOUBLE HEMIPLEGIA AND PSEUDO BULBAR PARALYSIS

By MURDOCH MACKINNON, M D Edin, D P H Oxon,

CASUALTY PHYSICIAN TO ST MARY'S HOSPITAL LONDON, LATE MEDICAL SUPERINTENDENT AND REGISTRAR, SEAMEN'S HOSPITAL, GREENWICH

Syphilis as it affects the nervous system was formerly considered to be a late secondary or tertiary manifestation of the disease, and the symptoms and signs of cerebral syphilis were calculated to become manifest usually between the third and tenth year after the primary infection It is now recognised, however, that brain syphilis may occur much earlier than this, and recent statistics show that about half the lesions occur within the first two years of the primary infection and the remainder are distributed over the next 12 years According to Mott half of the lesions occur within the first four years One of the commonest results of cerebral syphilis is hemiplegia, and although the period of its maximum frequency is between the third and tenth year cases occur within the first year, and even within the first few months instances have been reported The rarity of the latter, however, is well known, and the notes of the following cases, more especially of the first case, are interesting in that they show how early after the primary infection intracranial lesions may occur, and also the multiplicity of the lesions which is so characteristic of the disease, and serves to differentiate it from similar symptoms occurring in non syphilitic cases

Case 1 —A Chinese sailor aged 39 was admitted to the Hospital [illegible]

eyelid patient cannot [illegible] and pupils are equal and normal in reaction to light and accommodation Right corner of the mouth droops, and facial line is less distinct than on the left side Tongue is protruded to the right Right arm Loss of power in the arm but not absolutely paralysed Hand grip very weak There is no loss of sensation Right leg: Paresis as in right arm Knee-jerks increased Babinski's toe reflex No sensory changes *Left side* No paresis or sensory changes Reflex normal Chest Healthy No cardiac lesions On were sore. The mercury was stopped for a time, and he was given potassium iodide. On Dec. 19th he was discharged much improved. He could open the eye quite well now, and could use the right arm and leg almost as well as the left. He was given a mixture of biniodide of mercury, which he was to continue taking. On Jan. 2nd, 1911—that is two weeks after his discharge and three months after the appearance of right hemiplegia—the patient was again admitted to the hospital, but this time with a complete left hemiplegia and inability to talk. He was quite unable to speak, but from signs in answer to questions it appeared that the attack came on as before, during sleep, and on waking in the morning he found he could not move the left side at all and was unable to talk. There was complete paralysis of the tongue, soft palate, and lips. He could not protrude his tongue or move it to either side. The soft palate did not move and there was great difficulty in swallowing, especially liquids. Breathing was difficult and apparently was effected with great effort. Left arm: Marked loss of power. Could move fingers and wrist slightly. No loss of sensation. Left leg: Could raise the leg a little, but it was much weaker than the right. Babinski's toe reflex. Knee-jerks increased. No ankle clonus. Right arm: Fairly strong, but obviously weaker than normal. Biceps, triceps, and supinator jerks increased. Right leg: Fairly strong, but knee-jerks increased. Babinski's toe reflex. Ankle clonus. Sphincters unaffected. Jan. 15th: Patient improving slightly. Taking mercury and potassium iodide. He could swallow a little better, but was still unable to speak or protrude the tongue. The left arm was much stronger. Feb. 1st: General condition much improved. Could move the tongue slightly, but could not protrude it beyond the teeth. The left arm and leg were much stronger. On the 11th an injection of salvarsan ("606") 0 6 grm. was given. On the 18th he could talk a little and could protrude the tongue beyond the lips and swallow fluids and solids with comparative ease. The patient continued to make steady improvement and before his discharge on June 16th could walk and talk perfectly well, and beyond a slight exaggeration of reflexes on both sides and a little stiffness in walking there were no signs left of the successive attacks of paralysis.

In addition to the above case three others have come under my notice, all showing hemiplegic paralysis on one or other side, occurring at varying periods after the primary sore, but all of them undoubtedly secondary to the syphilitic infection.

CASE 2.—The patient, aged 30, was admitted to the hospital with loss of power in the right arm and leg. Nine contracted syphilis, for which he was treated and a half months. He was then discharged, continuing the treatment as before. Fourteen days before his admission he woke up in the morning with paralysis of the right arm and leg. There had been no premonitory symptoms. Physical signs: Divergence of tongue to affected side and facial paralysis. Paresis was never sufficient to inhibit progression, and under appropriate antisyphilitic treatment the patient rapidly improved. There was no cardiac disease or any evidence of arterio-sclerosis. Six weeks previous to this he had ptosis of the right eye. He states that previously to that he had paralysis of the left eye, from which he recovered.

CASE 3.—The patient, aged 40, was admitted to the hospital in December, 1909, suffering from paralysis of the right leg. It was elicited that in September, 1907, he had found that he could not open his right eye in the morning. There was no pain. For four months he was unable to open the eye completely. After that the condition slowly improved. He had been treated as an out-patient. In January, 1908, he had sailed to Cape Town, and while there was seized with sudden pain in the right leg with loss of power. He did not fall, and was able to walk to the hospital. From there he was sent home, and had since been taking medicine. In September, 1908, he had a transient attack of aphasia which lasted a few days and then cleared up. He had had a chancre; was uncertain as to date, but thought it was in 1903. On admission the patient was found to be a rather stout, robust man. There was no paralysis of the tongue, and the palate moved well. Eye: No diplopia. Right pupil slightly larger than left. Does not act so well. No ptosis. Slight weakness of right orbicularis palpebrarum. No facial paralysis. Arms: No tremor. Coordination perfect. Elbow- and wrist-jerks increased, especially right. leg much weaker than left. Slight foot skin. Knee-jerk exaggerated. Ankle clonu

CASE 4.—The patient, aged 30, was admitted to hospital on Dec. 21st, 1910, with loss of d leg. He had contracted syphilis had been treated for three and a ha then privately. Fourteen days before admission he lost the power of the right side during sleep. He had gone to bed quite well the night before, and there were no premonitory symptoms. The paralysis was not complete, as he was able to walk about fairly well, although very much weaker on that side. On admission the patient was found to be a well-nourished man. There was paresis of the right arm and leg. Facial folds flattened on the right, and the tongue was protruded towards the right side. The patellar reflex was much exaggerated on the right side, and ankle clonus was present. There was no ocular paralysis. There were no sensory changes. The patient was given a mixture of mercury and iodide of potassium three times a day and made rapid improvement. He was kept under treatment for six weeks, and on his discharge was perfectly well, having regained complete power of his limbs.

Hemiplegia due to syphilis, although as a rule presenting physical signs similar to those arising from hemiplegia due to other causes, at the same time differs in certain characteristics, and the first case narrated in this paper is typical in that respect. The brief notes of the cases which follow agree in the main with the above in respect to age, mode of onset, and termination, the succession of symptoms indicating multiple lesions and the complete recovery under suitable treatment

With regard to the etiology of syphilitic hemiplegia, it is well known that the vascular lesion, which is the commonest cause of this condition, is the obliterating endarteritis, a condition which may be found in a number of smaller arteries throughout the body, but most frequently in the smaller terminal arteries of the brain. The pathological change affecting the vessel walls begins as a proliferation of the adventitia. The increase of newly formed fibrous tissue frequently tends to the formation of a thrombus in the contracted lumen of the vessel, and according as to whether the thrombus partially or completely obliterates the lumen of the terminal artery the result is a hemiparesis or a complete hemiplegia. There may be a condition of unilateral numbness and tingling during the stage of partial obliteration due to the ischæmia of the part of the brain supplied by the obliterated vessel, and this condition may precede for several hours, or even days, the onset of sudden paralysis. This paralysis may readily be recovered from if the case is seen and diagnosed sufficiently early to allow of the appropriate antisyphilitic remedies being freely administered. Fortunately this is the result of treatment in most cases, but in a few the paralysis is permanent, on account of delay in treatment and the degeneration and softening of that part of the nervous system deprived of its blood supply. These vascular lesions are described as the early tertiary or late secondary manifestations of syphilis.

SYPHILIS: ITS DANGERS TO THE COMMUNITY, AND THE QUESTION OF STATE CONTROL.*

BY H. C. FRENCH, M.R.C.S. ENG., L.R.C.P. LOND.,

MAJOR, ROYAL ARMY MEDICAL CORPS.

(Concluded from p. 917.)

Resolutions adopted by the International Congress on the Prevention of Syphilis and Venereal Diseases; Brussels, September, 1899.

1. That the Government should use their utmost powers to suppress the prostitution of girls under age. 2. That a permanent international "Society of Social and Moral Prophylaxis" should be constituted, having its headquarters in Brussels, issuing a quarterly journal in French, English, and German, and holding congresses from time to time; the first congress to meet in Brussels in 1902. 3. That since a thorough knowledge (*connaissance approfondie*) of venereology is one of the most important means of effectually combating the spread of disease, complete and compulsory courses of instruction in the subject for all medical students should be instituted in every University, so as to ensure the training of really competent practitioners. 4. That guardians of orphans, and others charged with the education of the young, should use every effort to promote their moral development, and to teach them temperance and respect for women of all classes.[4] 5. That the utmost rigour of the law should be enforced against *souteneurs*.[5] 6. That the Governments should appoint in each country a commission charged to ascertain the amount of these diseases, apart from temporary fluctuations, among the *civil* population; to inquire into the existing means of treatment, the distribution of hospitals in various localities, &c., and to collect opinions and formulate proposals as to the best means of preventing the dissemination of the malady.[6] 7. That the Governments should find means to warn the public, and especially young persons, of the dangers attending an immoral life. 8. That the statistics of disease should be drawn up in all countries on a common basis. All these resolutions were passed unanimously.

---

* A report presented at a joint session of the sections of Dermatology and at the Seventeenth

[4] This was brought by a Russian delegate, Dr. de Sturmer, from a Russian Medical Congress, where it had been unanimously adopted.

[5] I.e., men who live upon the earnings of prostitutes.

[6] Proposed by Dr. Saundby on behalf of the British Medical Association.

Conclusions.

None of the final resolutions touched upon the question of State regulation at all. It was felt that if the Conference was to speak with authority it must speak "unanimously," and on this subject it was evident that opinions were hopelessly divided. Four of the resolutions aim at the "prevention of vice" as the root of the whole evil, while the remainder seek to increase the efficiency and accessibility of medical aid, to apply a "stimulus to research," and to bring all results into the common treasury. There is no reason to fear the light if only there is light enough.

We desire to rebut a common error and a not infrequent misstatement. M. Pierson, president of the International Society for the Abolition of Regulation, stated at the International Conference at Brussels, 1899, "that men infected with venereal disease were as dangerous as women, as they were not subject to regulation." This statement is erroneous for two reasons. First, a woman practising prostitution as a trade usually associates with numerous men. A man does not, and could not, associate with a like number of women. Secondly, *a woman does not, as a rule, know that she is suffering from venereal disease*, since she cannot see and rarely feels any discomfort. She consequently spreads a large amount of disease in ignorance and would not come under treatment unless she were medically inspected. A man, on the other hand, both knows, sees, and suffers from his venereal complaints, and usually seeks early advice. The European public prostitute, in her own interest, is necessarily only too ready to be cured when she knows she is diseased. This she cannot ascertain until others discover it. The clandestine prostitute, however, whether European or native, would never willingly *undergo treatment even when she knows she is diseased*. She practises her trade secretly, is not under any effectual control, and spreads ten times as much disease as a public prostitute. Such is the case in European countries, and it is endorsed by Indian experience. In speaking of the direct conveyance of acquired syphilis, gonorrhœa, and soft chancres (non-infecting sores) the amount of disease conveyed by a woman is, for the foregoing reasons, probably one hundred times as much as that conveyed by a man. This is important to remember in regard to the administrative control of venereal diseases, and a point that we have *rarely seen sufficiently recognised*.

Professor Fournier (Paris) said, "Statistics are good when they support you, and bad otherwise." When inaccurately collected it must be admitted that statistical evidence is most unsatisfactory and very conflicting. For the statistics of venereal disease to be really valuable they must be the result of personal inquiry, personally collected, the deductions fairly drawn and based on a sound system. In fact, if statistics are to prove anything they must be much more carefully revised and systematised. We indicate in what manner later on, in the scheme propounded for the army in the year 1904.

Prolonged treatment is only necessary in the case of syphilis. Non-infecting chancres (soft chancres) are seven to ten times as frequent as infecting chancres (primary syphilitic chancres, indurated chancre) in the case of soldiers in the British Army. This is probably the case as regards relative incidence amongst women. One or two months' adequate treatment and isolation would effectually cure nine-tenths of persons infected with venereal disease. In this category we include gonorrhœa for the purpose of isolation. Quite a small number of persons are infected otherwise than by "direct contact" with local lesions on the pudenda. The cure of these lesions is ordinarily quite an easy and a feasible task. Free prostitution undoubtedly means unrestricted syphilisation of the people. A syphilitic woman is a real source of danger, but any method of dealing with this question could only be successful by the early isolation of infected men and women, and by the efficient inspection of *both*.

It was further represented at the Conference in 1899 at Brussels that "The criminal phases of prostitution should be under the jurisdiction of the criminal courts and not as at present subject to the will of the police authorities and [illegible] veillance. Under the present [illegible] by criminal law is permitted."

Efficiency of control necessarily depends on the "competence of individual physicians." Unregistered prostitutes, however, came to dispensaries in a frightful state. It was conclusively shown that syphilis amongst women in Europe was most common between the ages of 17 and 22. The same applies to India. Prostitutes in Christiania, suffering from syphilis, who are arrested for other offences did not come under *treatment*. *Professor Peterson* said that regulations worked well in Russia and that supervision and inspection are of the greatest importance in preventing the spread of syphilis. It was generally admitted that medical inspection was "not as good as it might be." Many persons urged that it would be better to make inspection altogether a medical matter and to coordinate it with treatment by letting the women attend at special dispensaries. (This is done in India and with excellent results.) (Vide Appendices B and C and Tables III. and IV.)

Mr. C. F. Marshall[7] states: "Patients prefer to go to general hospitals or to skin hospitals, where they are treated as ordinary hospital patients and not as criminals and outcasts. This state of things results in the almost entire neglect of the study of venereal and syphilitic diseases in this country. On the Continent, and in America these diseases are recognised and studied in the *same way as other* diseases, and are not covered with the hypocritical cloak of British prudery." Mr. Brasher writes on May 29th, 1893: "A brief reflection will show that a large number of syphilitic patients would on no account voluntarily enter a lock hospital." He ventures to suggest that an important factor in the control of syphilis is to obtain greater "uniformity of treatment." "Greater uniformity of treatment and 'education of the public' on this subject will lessen but not prevent the recurrence of syphilis; more than this is needed. The fact that syphilis is an 'acute specific' points to notification under the Infectious Diseases (Notification) Act as the only logical course." It may be objected that notification will result in concealment, recourse to quacks, and inability of sanitary authorities to punish offenders. To this it may be replied that the success of the present notification is due to the public's recognition of the Act as a powerful preventive of the spread of disease, and therefore worthy of implicit obedience. Undoubtedly the prolonged course of syphilis and the impossibility of keeping patients under constant observation are difficulties, but if the public can be educated as regards tuberculosis they may also be taught that syphilis is as terrible a disease, and that it is also a preventable one.

Let us consider how the foregoing principles are supported by personal experience at Malta in the past three years. The enormous reduction in syphilis effected in recent years amongst soldiers in Malta has mainly resulted from the more thorough control of venereal diseases at their source in the civil community, which has enormously benefited. This has been effected by means of a system of "confidential medical notification" and more effectual segregation of diseased persons, commencing in October, 1909, and applied equally *to both sexes*. *A Government Ordinance* has existed in Malta since 1861, and this was amended in 1898 to make it in effect a sanitary ordinance on the lines of the Indian Cantonment Act of October, 1897 (*vide* Appendix B and Tables III., IV., V.)

Amongst troops in Malta in 1908 syphilis caused 18·6 admissions and 2·33 constantly sick in hospital per 1000. This was not high, but it has been reduced to one-fourth in 1911—namely, 4·3 admissions and 0·42 constantly sick per 1000, and no invalids for syphilis, gonorrhœa, or soft chancre. This result occurred in a garrison of 7000 soldiers amongst a civil population numbering nearly a quarter of a million of persons, and a fleet of 7000 strong arriving periodically. Not only was the incidence of freshly contracted disease lessened, but all forms of disease, syphilis, soft chancre, and gonorrhœa, were also attenuated. Table II. gives the actual number of soldiers on the Syphilis Register and the actual number of cases contracted in Malta, with such medical notification in force during my tenure of appointment since September, 1909, as contrasted with the admission and the constantly sick daily in hospital ratios. It can be observed that in 1910-1[illegible] incidence of s[illegible] admission and [illegible] partly depend[illegible] disease, are more largely influenced by administrative measures plus medical treatment, the sum total being largely dependent on the lubricating oil of individual initiative, on the introduction of measures to meet the frequently changing exigencies of local requirements, and on systematised procedure and centralisation of work.

---

[7] Brit. Med. Jour., May 23rd, 1899.

The naval and civil authorities also report the marked reduction of disease; and provided that the immigration of diseased persons from ouside areas can be controlled, poverty and its twin sister, disease, will eventually be lessened by a reduction in the cost of maintenance of poor-houses, prisons, and lunatic asylums (in which places syphilis is domiciled), and the illegitimate birth-rate lessened. What has been done in the island of Malta can be equally done in the British Isles—with effort.

In Malta several other factors have also contributed to good results, and in the case of syphilis they have been obtained with mercury, potassium iodide, and local treatment. The results under mercury endorse those obtained at Woolwich (Table I.) in 1905-9, and endorse Indian experience (Table III.). The marked reduction in syphilis from 1909 to 1911 in Malta, in India 1898 to 1910, and throughout the army generally as exemplified by these tables, occurred before the introduction of salvarsan. A "Syphilitic Record Book," introduced in 1904, and modified in 1910, exists in each station, and the particulars from the "syphilis case-sheet" are entered for permanent reference. These general principles have recently been applied to gonorrhœa, and a "gonorrhœa case-sheet" as an official army form is now in use. Finally, by means of a "venereal surveillance form," cases are followed up on discharge from hospital or on transfer to other stations.

It may prove of interest to trace the origin of methods which, in a modified degree or in a different manner, could be easily made applicable to the control of venereal diseases in civil communities. In July, 1903, I applied to the War Office for permission to publish some printed matter, the results of investigations in India from 1896 to 1901, and previously, on the control of venereal diseases in the Army. The absolute necessity of entirely revising the collection of venereal statistics, systematic case-taking, and accurate diagnosis was emphasised. Up to this date all cases of venereal sores, whether soft chancre or early primary syphilis, were indiscriminately recorded as primary syphilis or primary venereal sores. If secondary syphilis followed, then a change to secondary syphilis was made if the case happened to be in hospital. This was confusing and misleading. In September, 1903, therefore, a preliminary tentative scheme was brought into force—"Instructions regarding Procedure in Cases of Syphilis." Under this scheme syphilis and soft chancre became absolutely differentiated. From Jan. 1st, 1904, the scheme was made universal throughout the whole army at home and abroad, and was later incorporated into Appendix VII., Regulations Army Medical Services. Under this scheme all venereal sore cases after discharge from hospital are now kept under weekly observation, according to time spent in hospital, for two or four months before the diagnosis of soft chancre, or syphilis, is finally made. This is very important in limiting the local spread of disease arising from relapsed chancres, or a recrudescence of disease. Latterly, I have kept gonorrhœa cases under weekly observation for six weeks from date of discharge from hospital, with excellent results in lessening disease both in the case of the soldier and the local civil community.

If, therefore, the legislature in this country is later guided by our deliberations, the administrative system of control existing in the army can easily be adopted or improved on to meet the special requirements of civil communities in England. It is first necessary, however, to get legal control of syphilis in a manner that small-pox and other much less dangerous diseases are controlled. It is absolutely essential, from a public health point of view, to go to the legislature of the country with concrete proposals and undivided counsels.

In summarising the means at our disposal it is requisite to bear in mind that there are three main principles involved in the prevention and control of venereal diseases. First, control at the source which is concerned with prostitution before disease is contracted or spread. This embraces (*a*) medical notification of disease; (*b*) suppression of *souteneurs* and solicitation in the streets; (*c*) protection of orphans and destitute children; (*d*) police measures. Secondly, prevention by medical measures—i.e., prophylaxis by treatment after disease has been contracted. This includes: (*a*) provision of hospital beds and segregation; (*b*) professorships at large hospitals; (*c*) instruction of students and the public; (*d*) treatment. Thirdly, moral and religious considerations. These are placed last, but are by no means least, and are more applicable to youth and adolescence before disease is contracted. At the Brussels International Conference in 1899 the consensus of medical evidence was distinctly in favour of revised regulations for dealing with prostitution apart from the State control of vice (vide Appendix A). The abolitionists of regulation strongly advocated the *notification* of venereal diseases, female inspectors of factories, and reformatories for young girls aged under 21 who adopt a vicious life, where they could be taught a trade and be reclaimed.

If we recognise the cardinal fact that prostitution has always existed, and unfortunately must continue to do so for all time—since, as previously explained, it is largely dependent on poverty—it then becomes self-evident that to control disease which is the direct outcome of uncontrolled prostitution it becomes necessary to first effectually control all persons who practise it. This is the really important consideration as regards the community. The individual aspect in the interests of public health must be sacrificed to the general principles which govern our action. In law the individual aspect is frequently sacrificed to the general issues. This principle is rightly recognised and its utility is obvious. In public health questions, however, we yearly sacrifice thousands of lives and destroy a carefully constructed social fabric at every turn, because we do not recognise an elementary truth, or in recognising it fail to act. In the absence of the fulfilment of an impossible ideal such as the entire suppresion of prostitution, it is necessary to control its undue exercise by effectually preventing open solicitation in the streets, as in London, and limit prostitution by localising it. This is a police matter. Clandestine prostitution must be absolutely suppressed with a firm hand. To do this we must legally deal with the procurers of it, who are numerous, and with the incentives to it, which are many. Until public opinion is better informed it is hopeless to expect that any real progress will be made, our prisons will be full of prostitute women, as at present, and lunacy will continue to increase.

In conclusion, I quote from Mr. Lecky's History of Morals[8]: He deplores the fact "that an epidemic, which is one of the most dreadful now existing amongst mankind, which communicates itself from the guilty husband to the innocent wife, and even transmits its taint to her offspring, should be suffered to rage unchecked because the legislature refuses to take official cognisance of its existence, or proper sanitary measures for its repression."

APPENDIX A.—*Foreign Countries.*

In regard to systems of regulation of prostitution in foreign countries: At the International Meeting at Brussels in 1899 the question before the meeting was: Have the systems of regulation actually in force had any influence upon the frequency and dissemination of syphilis and venereal disease?

[illegible] l chiefs at St. Lazare Hospital, [illegible] ly inspection properly without [illegible] unrestricted syphilisation of the [illegible] made women professional prostitutes, as they were so before. Disease was due to immorality, not to regulation; passion was an eternal and imperative factor in human life, and regulation was a means of combating its attendant evils. If it had not yet succeeded, that was not a reason for abolishing but for improving it." He recommended "gentler" methods.

I understand that the old prison hospital at St. Lazare, Paris, is to go, and a hospital to be built for diseased prostitutes.

Professor Fournier "would not trust to statistics, but appealed to common sense. An infected prostitute was safe only when she was shut up." He stated that the opponents of regulation (abolitionists) minimised the appalling deformities and dangers of syphilis. Professor Lassar (Berlin) agreed with Professor Fournier, and considered "that an infected prostitute was a focus of disease which it was the duty of society to remove." Professor Neisser (Breslau) shared Professor Fournier's opinions and was opposed to the views of the abolitionists.

The Italian doctors drew attention to the very serious increase of disease in Italy on the abolition of Cavour's system by Signor Crispi in 1888. The same thing occurred in India in 1885, when 15 of the principal hospitals were closed as an experiment. The experiment being unsuccessful, the hospitals were reopened until 1888, and then closed until 1897. During this period the increase of disease was appalling. Control again began in October, 1897 (vide Tables III. and V.). Dr. Bortavelli (Milan) supported regulation. Professor Oltramana (Geneva) said that the question had lately been put to the vote in Geneva and regulation affirmed by a majority of two to one. He considered "that the success of regulation depended greatly upon the competence and carefulness of the physicians to whom the work was entrusted."

---

[8] Vol. ii., pp. 280 et seq.

Professor Holst (Christiania) said that since the abolition of regulation in Christiania syphilis had increased 25 per cent. and clandestine [illegible] Professor Sturmer (St. Petersburg) [illegible] at unregistered prostitutes came to [illegible] ate." Professor Peterson said that [illegible] and moved "that supervision and [illegible] ortance in preventing the spread of syphilis.

To reduce the number of prostitutes the abolitionists of regulation [illegible] efforts [illegible] stage. [illegible] the provision of female inspectors of factories, more employment for women, and the notification of venereal disease.

Dr. Jullien (Paris) produced tables to prove that venereal disease [illegible]

[illegible] ase of women denounced [illegible] nation should be in the [illegible] ctual treatment was the [illegible] e essential—namely, im[illegible] ly of competent doctors, [illegible] knowledge."

APPENDIX B.—*The Cantonment Code, 1899, India: In force October, 1897.*

Par. 175. No public prostitute shall be permitted to reside within the [illegible]

[illegible] disease.

Par. 203. If the medical officer in charge of a hospital or dispensary [illegible] of practice becoming cognisant of the existence of an infectious or contagious disor[illegible] dispensary, in the [illegible] of such medical p[illegible] dwelling and bein[illegible] contagious disorder [illegible] being the person in charge of, or in attendance on, any person [illegible] to spread the disease. In this section the expression "infectious or [illegible] ound to make an [illegible] olice station, of any [illegible] provide or prescribe suitable routes for the use of persons passing through the cantonment (*a*) on their way to or from fairs or places of pilgrimage or other places of public resort, or (*b*) dur[illegible] disorder is prevalent, and [illegible] aforesaid to use such route [illegible] prescribed under Subsec[illegible] indicated by the cantonment authority.

Par 173. (1) In the event of the cantonment being at any time visited or threatened by an outbreak of any infectious or contagious disorder among the inhabitants thereof, or of any epidemic disease among the cattle, sheep, or goats therein, the general officer of the command, if he thinks that the provisions of this or of any law at the time in force are insufficient for the purpose, may, with the previous [illegible] Code.

Par. 208. No mendicant shall in any street or public place in the cantonment loiter or beg for alms.

Par. 210. The cantonment magistrate may on receiving information that any person whether resider[illegible] ent "is a disorderly person keeping [illegible] of any description" may prohibit [illegible] re-entering a cantonment, after r[illegible] cer commanding the station.

[illegible] re-entering the cantonment, fails to remove from or re-enters it [illegible] ding officer of the [illegible] for a term which [illegible]

British Colonies.

[illegible] complaint being made, and penalising persons importuning or "soliciting" for immoral purposes

Ceylon.—In Ceylon there is no special Ordinance for dealing with venereal disease. Ordinance No 5 of 1889, however, confers the power of "closing brothels reasonably suspected of being special centres of disease."

[illegible] Hospital one lock ward is maintained for males, and two in a separate block for females. Males, unless certified to be indigent, pay for their subsistence; females are treated and supported in hospital gratuitously. [illegible]

Again, in China, Hong-Kong, and in the Straits Settlements, control in anoth [illegible] Women's and Girls' Protection Ordin [illegible] of control by medical prophylaxis [illegible] exemplified.

APPENDIX C.—*Contagious Diseases Acts of 1864–66 and 1869 in England.*

Major (now Colonel) Macpherson, R.A.M.C., produced a diagram at the Brussels Conference in 1899 to show the curve of venereal incidence in 14 regulated and 14 non-regulated towns in Great Britain. The results closely approximated before and after the period in which the Contagious Diseases Acts were in force, but during the period separated widely in consequence of the lowering of the rate in the regulated towns.

Dr. Kromayer (Halle) exhibited a number of tables in 1899 to show "that the Contagious Diseases Acts in England had a distinctly beneficial effect upon the incidence of syphilis, but had not affected the frequency of soft sores or gonorrhœa."

A Royal Commission in 1870 reported on the working of the Contagious Diseases Acts of 1864, 1865, and 1869, and expressed the opinion "that the worst forms of the disease had been much reduced amongst the lower clas [illegible] women had also been benefited in an indirect [illegible] duced from 40 per 1000 in 1864 to 20 per 1000 [illegible] the United Kingdom. "The Acts have pur [illegible] nents to which they have been applied of miserable creatures who were mere masses of rottenness and vehicles of disease." The report further says, "We are satisfied from the evidence that the frequent examination of prostitute women is the most efficacious means of controlling the disease."

The Contagious Diseases Acts did not die a quick death in England. They were in force from 1864 to 1886, and their repeal was mainly due to political reasons. The late Sir Alfred Cooper in his work on "Syphilis" in 1895 gives full details with statistics on this subject.

FOREIGN BODIES IN THE AIR PASSAGES.

BY W. G. HOWARTH, M.A., M.B., B.C. CAMB., F.R.C.S. ENG.,

SURGEON IN CHARGE OF THE NOSE AND THROAT DEPARTMENT AT ST. THOMAS'S HOSPITAL; SURGEON-LARYNGOLOGIST TO THE VICTORIA PARK HOSPITAL.

DURING the last few years the recognition and treatment of foreign bodies in the air passages have become a much simpler matter than heretofore. This is mainly due to larger experience in the use of the instruments invented by Killian, Brünings, and others for the practice of the direct method, and to the improvement that has taken place in skiagraphy. Within the last decade the number of recorded cases has grown greatly, and it would scarcely be necessary to mention the following four cases with which I have recently had to deal were it not that one at least of them presents some unusual and interesting features. In two of the cases there was a definite history of the accident and a fairly accurate description of the appearance and size of the object; in the third case the possibility was thought of when the patient was seen for another reason, whilst in the fourth case the symptoms alone brought the subject under notice.

CASE 1.—The patient was a child, aged 9 months, who, after sitting on some rugs in the garden, had been brought into the house and put to bed; shortly afterwards the mother heard a strange noise and found the little one gasping for bre [illegible] noise when crying. A few hours [illegible] (Fig. 1) was taken. [illegible] was inserted and a [illegible] is seen to be impacted in the subglottic space, the upper and [illegible] between the vocal cords. The foreign body [illegible] pair of Brüning's forceps, and proved to be [illegible] toy trumpet which had been flattened by being trodden on.

CASE 2.—The patient, aged 50, came to the hospital one morning to apply for a new tracheotomy tube which he wore permanently on account of laryngeal stenosis. It was noticed that a portion of the old tube was missing, and as he said that he had had a cough for some days an X ray photograph (Fig. 2) was taken. The tracheotomy wound and the upper part of the trachea were painted with 10 per cent. cocaine, a bronchoscope was inserted, and the foreign body, located in the right main bronchus, was extracted with forceps.

CASE 3.—The patient, aged 20, was using a hairpin as a toothpick when her brother spoke to her and made her laugh. She swallowed the hairpin and had a short fit of coughing. She came to the hospital three days after the acciden [illegible] in the left side on respiration. An X ray [illegible] taken, and on the next day, under light [illegible] after scopolamine morphine, a bronchoscope was passed. One point of the hairpin was located in the left bronchus 29 cm. from the teeth. There was a considerable degree of inflammation of the bronchial mucosa and a great deal of mucopurulent secretion, so that it was not possible to be certain where the distal end of the hairpin was situated, but as one arm of the pin seemed to be lying obliquely across the lumen of the tube it seemed probable that the distal end was in the lower lobe bronchus. Both points seemed to be impacted in the bronchial wall. Attempts to dislodge it by gentle traction with the ordinary Brüning's forceps were not successful, and as it was thought probable that a better result might be obtained by the use of a snare further efforts were postponed for a few days. In the meantime Messrs. Mayer and Meltzer constructed several powerful snares 35 cm. long, and a few days later a bronchoscope was passed and an attempt made to get the loop of the snare over one of the points and so draw the hairpin into a straight line with the tube. This manœuvre was not successful, and so a low tracheotomy was performed and the tube passed through this. It was then possible by using a tube with a sloping end to disimpact the points of the pin, pass the sharp edge of the tube over one point, grasp the other point with Brüning's forceps, and draw it into the bevelled side of the tube. The tube and hairpin were then withdrawn. The tracheotomy wound was closed. There were no after symptoms and the patient felt perfectly well the next day.

CASE 4.—A boy, aged 10½, was holding a shawl-pin in his mouth, preparatory to putting it in his tie, when he took a deep breath and swallowed it; he had a slight fit of coughing but experienced no pain in the throat or in the chest. He was seen next day and an X ray photograph (Fig. 4) was taken. Under light chloroform anæsthesia a bronchoscopic tube was passed through the larynx, the pin located point uppermost in the left main bronchus grasped with a pair of forceps, and withdrawn through the tube. The bronchial wall did not appear to be inflamed and there was no excessive amount of secretion.

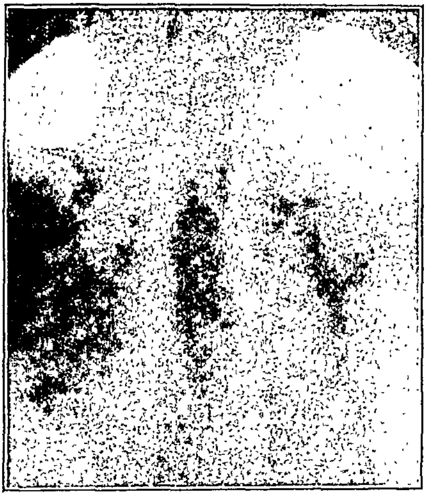
A necessary preliminary to the efficient treatment of a foreign body that has been inhaled is an exact idea of the size and shape of the object and its accurate localisation. When these two matters have been satisfactorily decided, the actual extraction is not in the majority of cases a matter of any great difficulty provided that the surgeon has efficient instruments and has had some practice in the use of them. A history of the accident often defines the nature of the foreign body, but a history is not very often obtainable in the case of small children, as the accident usually occurs when they are not under observation. When a foreign body is suspected an X ray photograph should always be taken. In small children instantaneous photographs do not always give good results, and an anæsthetic may be necessary before a satisfactory result is obtained. Attention should be paid to the position of the child, so that the bony landmarks may be as definite as possible. A lateral view should always be taken as well as an antero-posterior one. In Case 1 the illustration (Fig. 1) gives but little idea of the real size or shape of the object, but it was quite evident from looking at a lateral view that the object was a flat piece of metal almost half an inch across with its sharp edge sticking forward. A lateral view also in many cases indicates whether the object is in the trachea or œsophagus, especially in the cervical region. As regards localisation, however, an X ray photograph can only give a rough idea, and the position cannot be accurately determined until a tube is inserted and a careful examination made.

In all the above cases great help was afforded by the X ray photographs, but the objects were fortunately all metal ones and cast definite shadows. Other kinds of foreign bodies, such as beans, nutshells, or other vegetable material, are extremely difficult to see in a skiagram, and even pieces of bone, especially if they have become decalcified, are often very hard to recognise; this is particularly the case with foreign bodies in the larger bronchi, as these are apt to be much obscured by the heart shadow. In rather more than 50 per cent. of all cases a good skiagram will show a positive result, but considerable skill is required in the taking of them, and in this connexion I would express my indebtedness to Mr. Archibald Reid for the excellent ones that he provided for my cases.

In attempting accurate localisation it is well to begin by inserting a short tube spatula so that the mouth of the œsophagus and the larynx may be examined and the size of the latter estimated. If the larynx is clear the cords should be lightly swabbed with 10 per cent. cocaine and the largest size tube that seems advisable introduced. It is entirely unnecessary to drench the bronchial tree with cocaine as the mucosa is not nearly so sensitive as is usually supposed. After the main bronchi are reached excessive secretion and inflamed œdematous mucous membrane often obscure the view; the secretion should be aspirated or removed with wool mops, whilst a pledget of wool soaked in adrenalin to which a few drops of cocaine have been added markedly reduces the congestion and blanches the mucosa, thereby enabling the ring markings which are the surgeon's main rallying points to be recognised. If the main bronchi yield a negative result careful attention should be directed to the lower lobe bronchi and the middle lobe bronchus on the right side; the upper lobe bronchi are very rarely affected, which is perhaps fortunate, as they are by no means easy to explore. When the position of the object has been accurately defined the question of extraction is reached. The above cases afford examples of one of the easiest and one of the most difficult types.

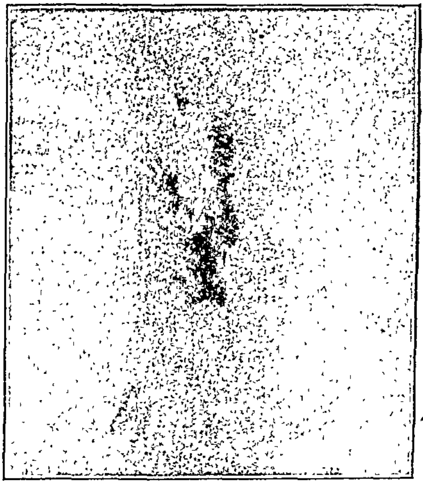
When once located it was the work of but a few moments to define the upper edge of the tracheotomy tube (Fig. 2) by

FIG 1.



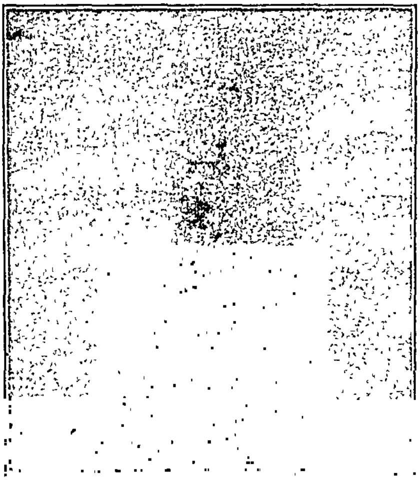
CASE 1.—Mouthpiece of a toy trumpet impacted in subglottic space.

FIG. 2.



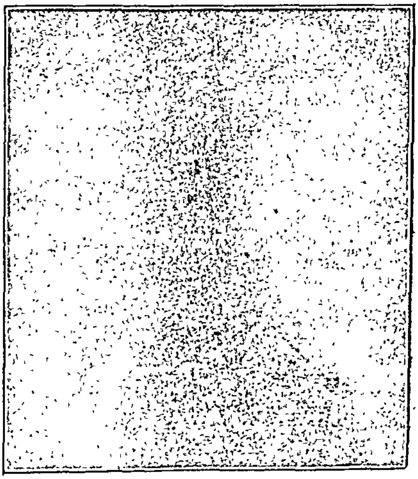
CASE 2.—Portion of a tracheotomy tube in the right main bronchus.

FIG. 3.



CASE 3.—Hairpin impacted in left lower bronchial wall.

FIG 4.



CASE 4.—Shawl-pin in the left main bronchus.

lateral pressure on the bronchial wall, to slip one blade of the forceps outside it and extract it. The localisation was not quite so easy, as the tube closely fitted the bronchus in which it had come to rest, caused no obstruction to the airway, and had its thin upper end obscured by slight overhanging of the bronchial mucosa. The hairpin (Fig. 3) was a more difficult matter, as both ends sticking upwards were impacted at different levels in the bronchial wall, which was acutely inflamed and obscured by mucopurulent secretion. The distance of the object, and the small size of the tube that could be employed prevented both ends from being seen at the same time, and the obliquity was such that traction on one end would only result in the other end becoming more firmly impacted. As attempts to approximate the ends by slipping a snare over them were unavailing it was decided to open the trachea low down. It was thought that lower bronchoscopy would afford greater power of mobility of the trachea, and there would be no possibility of the larynx being injured, as might easily have been the case, even if extraction by the upper method had been successful. A tube was inserted through the tracheotomy wound, one end of the hairpin grasped and pushed forcibly downwards, so that both ends might become disimpacted. By using a tube with an end cut very obliquely it was possible by the aid of forceps to get the sharp edge between one end of the hairpin and the bronchial wall. The tube was then pushed down and rotated until the other end of the hairpin was opposite the obliquely cut side of the tube. It was then seized with forceps and drawn into the tube, considerable lateral pressure being exerted on the bronchial wall. The obliquely cut tube made the procedure easier than would have otherwise been the case. Paterson was the first to see the advantage of an inner tube with the end cut obliquely, and his reversal of the usual Brüning's tube which has the outer one oblique and the inner straight ended is in many cases certainly an advantage.

The other bronchial case was quite straightforward, as the rounded-glass end of the shawl-pin was in the lower lobe bronchus and the point sticking upwards (Fig. 4), so that there was no objection to upper bronchoscopy, and the pin was drawn through the tube.

The laryngeal case was rendered more troublesome by the size and jaggedness of the object, the firmness of impaction, and the delicacy of the larynx in a child of 9 months. A small tube spatula was used and just before the moment of extraction this was rotated laterally and its end pushed between the cords without loosening the hold of the forceps on the foreign body; in this way the cords were momentarily held apart whilst the object was disimpacted and guided between them without any injury occurring. It might have been expected that trouble would be caused by subsequent subglottic œdema, but fortunately this was not the case.

Harley-street, W.

ACUTE EPIDIDYMO-ORCHITIS DUE TO BACILLUS COLI.

BY W. P. BONNER, M.R.C.S. ENG., L.R.C.P. LOND.

THE patient, a man aged 45, was admitted into the London Hospital on April 24th last, under the care of Mr. Hugh Lett. Twenty days previously he "strained" himself while lifting a heavy box at work. This caused him pain in the lower abdomen which was so severe that it made him sweat. The pain ceased after a few minutes, and after passing a large amount of urine he continued with his work as usual. Four days later he complained of frequency in micturition, at first every half hour, then seven to eight times a day and two to three times during the night. He consulted his medical man about this; "the doctor gave him medicine" (no injection). Two days later he had pain in the right testicle, which came on during the night. The right side of the scrotum gradually became swollen and red. He never had any urethral discharge or pain on micturition. There was no previous history of any venereal disease; he married at the age of 20, has had a family of 13 children, and his wife is living and in excellent health. No history of coitus since 10 days previous to the onset of the frequency in micturition. No family history of any tuberculous disease.

On examination (April 24th) the patient was a poorly developed, ill-nourished man. Temperature 100·4° F., pulse 94. The urine was acid, of specific gravity 1020, and contained a considerable amount of pus and mucus. The right half of the scrotum was swollen, red, very tender, and hot; the skin was adherent at the lower and posterior part. The right epididymis was extremely tender and enlarged so much that it almost covered the right testicle. The right testicle was swollen and tender (no hydrocele). The right spermatic cord was swollen and tender throughout the whole extent, which might be felt below the external abdominal ring. The right inguinal canal was tender on palpation. The urethra had a healthy appearance and was just moistened with clear mucus. No purulent fluid could be expressed by squeezing the penis. The prostate and vesiculæ seminales (felt per rectum) were not enlarged or tender. The left side of the scrotum and its contents showed nothing remarkable.

On April 30th the anterior portion of the urethra was washed out thoroughly with boric lotion. A sterilised soft indiarubber catheter of large size was passed without any difficulty, and a specimen of acid urine was drawn off. This specimen on microscopic examination showed a few pus cells and a quantity of coliform bacilli. Pure cultures of coliform bacilli were subsequently grown from this same specimen and an autogenous vaccine was prepared. On May 13th a soft fluctuating swelling appeared at the lower and posterior part of the right side of the scrotum. The skin over this area having been carefully prepared, the swelling was aspirated and a small amount of cloudy fluid obtained. Pure cultures of the coliform bacilli grew from this fluid. On May 15th the swelling (now more marked) at the lower end of the right scrotum was incised under a general anæsthetic. A small amount of material was removed which appeared to be almost entirely composed of disorganised tubules. No actual fluid pus was seen. On microscopic examination this material was found to be composed of a mass of necrosed tubules of testis and epididymis, coliform bacilli, and a few pus cells. Subsequently pure cultures of coliform bacilli were grown from this material. The urethra examined by the urethroscope appeared to be quite healthy; there was no stricture and no evidence of old or recent gonorrhœal trouble. Prostatic fluid obtained by massage of the prostate showed a few pus and epithelial cells, coliform bacilli, and staphylococci (no gonococci). Cultures taken from this fluid produced colonies of the coliform bacilli and staphylococcus albus. The coliform bacilli obtained on each of these four separate occasions were identical in structure and gave the reactions of Friedlände on sugars. Carefully taken radiographs showed no sign of any pathological conditions in the regions of the kidneys, ureters, or bladder.

The treatment of this case was as follows:—Rest in bed with the scrotum well suspended. Locally, at first, the application of moist heat in the form of boric fomentations and later (after incision) daily dry dressing with plain sterilised gauze. Medicinal: Maintaining the reaction of the urine alkaline by the administration of citrates and bicarbonates; bladder sedatives, hyoscyamus and buchu. Vaccine: Gradually increasing doses of the autogenous bacillus coli vaccine were given once a week, commencing with 5 millions and increasing up to 100 millions.

The patient has made an excellent recovery, the affected area of the right testis and epididymis being now represented by a small fibrotic nodule. The left epididymis and testis remain unaffected.

This case seems to suggest that some of the conditions of acute epididymo-orchitis of obscure origin, frequently associated with a history of strain, are due to an infection with the bacillus coli, brought on by a strain while the bladder is full of urine. I am indebted to Mr. Lett for permission to publish the case and for urethroscopic examination; to Mr. F. S. Kidd for investigating the prostatic fluid and also examining the urethra; and to Mr. T. H. C. Benians for the preparation of the autogenous vaccine and the bacteriological investigations.

A GERMAN FEMALE MEDICAL OFFICER OF SCHOOLS.—The municipal authority of Berlin has appointed Fräulein Martha Ulrich, M.D., as school medical officer, she being the first medical woman to obtain one of these school appointments.

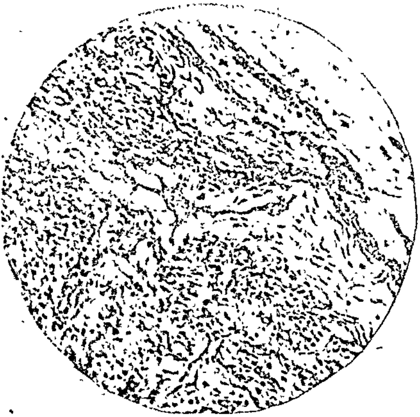
A NEUROMA-MYOMA OF THE MESENTERY.

BY PETER PATERSON, M.B., C.M. GLASG.,
F.R.F.P.S. GLASG.,
SURGEON, GLASGOW ROYAL INFIRMARY.

THE patient was a boy, aged 9 years, whose development was distinctly below the average. He was unable to speak till he was 6 years old, and now he has as classmates boys who are two to three years his junior. His physical condition is as poor as his mental. Till he was 16 months old he suffered much from gastro-intestinal derangements, but as his parents belong to a class whose idea of a suitable diet for infants is of the most elementary kind probably these derangements were due to unsuitable food. From that time he seems to have remained well till the beginning of this year, when he was admitted to the Royal Infirmary with symptoms which suggested an attack of appendicitis. He had pain, tenderness, and rigidity in the right iliac fossa, constipation, and vomiting. Temperature, 101·6° F. ; pulse, 136. Leucocytes 20,800, with a distinct increase in the percentage of the polymorphs.

He was operated on soon after admission by one of my assistants, who removed the appendix. This was found slightly congested, but otherwise was normal. During his residence in hospital he remained free from pain, but five months later he was readmitted with symptoms somewhat similar to those of which he complained on the previous occasion.

FIG. 1.

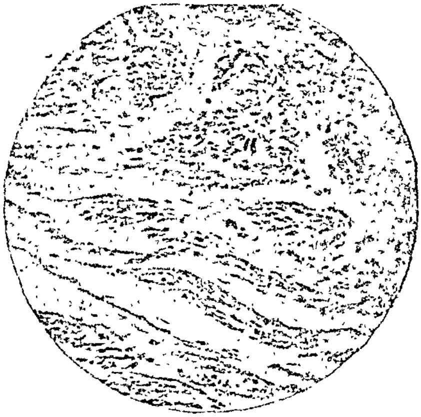


Section from centre of tumour showing medullated nerve fibres and ganglionic cell.

It seems that after leaving hospital the boy had severe attacks of abdominal pain, accompanied with vomiting and constipation, every seven to ten days. These attacks came on suddenly and passed off within 24 hours, leaving him apparently well. Soon after admission he had one of these attacks. The pain was so severe as to make him throw himself about in bed. It was continuous, but with exacerbations, and was felt all over the abdomen, though most marked in the lower half. Vomiting was frequent and bilious in character. There was no rise of temperature The attack lasted 24 hours, and during that time the bowels did not act. On examination of the abdomen a smooth oval tumour could be felt in the middle line, slightly below the umbilicus. It was tender on pressure and fairly freely movable. At the operation the mass was found lying in the mesentery with its long axis parallel to the vessels and its distal end about one inch from the intestinal border As it was encapsulated it was easily enucleated. The post-operative history was uneventful, except that for two days the patient was very sick.

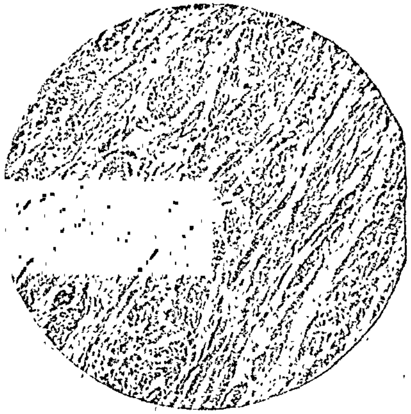
The tumour was smooth, oval in shape, and measured 6·5 cm. by 4 cm. When laid open a small part at the centre presented a soft, reddish appearance, while the larger peripheral part felt and looked like a hard fibroma. Sections were made from various parts of the tumour. Those taken from the soft, reddish centre were composed, almost entirely, of medullated nerve fibres, with a very few ganglionic cells. (*Fig.* 1.) The fibres ran in ill-defined bundles, these interlacing one with another, and bound together by connective tissue. In sections taken from parts nearer the periphery strands of plain muscle fibres appeared amongst the nerve bundles, and these gradually increased on passing outwards till, under the capsule, the tissue was almost entirely muscle. (Figs. 2 and 3.) The blood-vessels were numerous, but were not well developed, the intima being the only coat that could be definitely recognised.

FIG. 2.



Section from outer part of tumour showing strands of plain muscle fibres among the nerve bundles.

FIG. 3.



Section of tumour under the capsule where the tissue was *nearly all muscle.*

Both myomata and neuromata have been removed from the mesentery, but, so far as I am aware, a tumour composed of both those highly differentiated tissues is unique.

Glasgow.

THE RETRACTION RING AS A CAUSE OF OBSTRUCTION IN LABOUR.[1]

BY ROBERT JARDINE, M.D. EDIN., &c.,
PROFESSOR OF MIDWIFERY, ST. MUNGO'S COLLEGE; OBSTETRIC PHYSICIAN AND GYNÆCOLOGIST, GLASGOW MATERNITY AND WOMEN'S HOSPITAL, ETC.

I SHALL deal with this subject from the clinical side and leave the anatomical aspect of it to Dr. A. H. F. Barbour and other speakers. As to the situation of the ring, all that it is necessary for me to state is that it marks the junction of the active or retracting portion of the uterus with the portion which is passive and stretches. The part of the uterus below the ring constitutes the lower uterine segment. In an obstructed labour, say from a contracted pelvis, where the lower uterine segment is markedly thinned out and the upper segment well retracted, a sulcus can be seen and felt extending across the abdomen well up towards the umbilicus. This marks the situation of the ring. It may lie transversely or more or less obliquely. If an internal examination be made a ledge will be felt running round the uterine cavity at the upper limit of the lower uterine segment. In some cases it extends completely round, while in others, as in the specimen I show, it is not complete. It can be detected by an internal examination before its presence can be made out by palpation through the abdominal wall. I need hardly say that such an internal examination must be made with extreme care, when the ring is above the presenting part, as there is great risk of rupturing the lower uterine segment. That is what happened in the case from which the specimen I show was obtained. (See figure). It was a face presentation in a mento-posterior position, and after the ring had formed above the head forceps were tried, and then an attempt was made to do version. When the operator passed his hand in to catch a foot the patient suddenly collapsed. She was then brought into the hospital from the country, and she died in the waiting-room a few minutes after admission. We were allowed to remove the uterus, and after it was hardened it was opened, and a rupture through the muscular wall of the lower uterine segment was found of the exact shape of the back of a closed hand. The operator had recognised that there was a deep sulcus across the abdomen below the umbilicus before he passed his hand in, but he had failed to grasp its significance.

In ordinary cases of obstructed labour the ring is not the primary cause of the obstruction, but the result. However, it is not to such cases I wish specially to refer, but to those in which the ring is the primary cause of obstruction. These latter cases are not so common as the former, but when they do occur they are very much more difficult to recognise and also to deal with. So little attention has been paid to such cases that you will hardly find any reference to them in even the most recent text-books on midwifery. In some instances the ring actually forms in front of the presenting part, while in others it forms above the presenting part, just as it does in an ordinary case of obstructed labour. The presenting part may be either the head or the breech.

I. *Cases in which the Retraction Ring forms in Front of the Presenting Head.*

I have seen two such cases, both in hospital, one under my own care and the other under the care of my colleague, Professor M Cameron.

In my case the patient was a v.-para. Her four labours had resulted in the birth of dead children, but only the fourth one had been at full time. The pelvis was flattened with a true conjugate of 3½ inches. About a fortnight before full time I admitted the patient for a thorough examination, to decide whether or not to induce labour. I found the head could be pushed into the brim of the pelvis, so I advised her to wait to full time. The lower uterine segment began to dilate, and on making an examination a few days before labour was due I found the os would admit two fingers, and the cervix was taken up. The head lay at the brim, and it could still be pushed into it. There seemed every likelihood that the delivery would not be difficult. At the expected time labour pains began, but they ceased after a few hours. To hasten matters the largest Barnes's bag was inserted late in the afternoon, but it was quickly expelled. The pains continued throughout the night, and at noon of the following day the os was fully dilated, and the membranes were bulging well into the vagina. The head was now well above the brim, and in front of it was a well-defined ledge extending round about one-half of the cavity. The head could not be pushed into the brim, as the ring prevented its descent. A full dose of morphia was given, but four hours later there was no relaxation of the ring, so I performed Cæsarean section. At the time of the operation the membranes were still intact. At the request of the patient I sterilised her by ligaturing and cutting the Fallopian tubes. Both mother and child did well.

If this patient had had a normal pelvis I would have tried to dilate the ring manually, and if I had failed I would then have done Cæsarean section; but further experience has shown me that when the ring is once well formed it cannot be dilated manually, and if I should ever meet with a case with a normal pelvis I would advise Cæsarean section.

Professor Cameron's case was a very similar one as regards the size of the pelvis, but when we examined the patient the membranes had been ruptured for several hours. The os was fully dilated, but there was a distinct ledge running round about half the cavity in front of the head. The ledge prevented the descent of the head. As in my case, the cervix and lower uterine segment were well dilated. Morphia was tried, but it had no effect, so Cæsarean section was done by Professor Cameron. Both mother and child did well.

In both of these cases the pelvis was contracted; but it was quite evident that the obstruction did not arise from the pelvis but from the ring, and I do not think that the pelvic condition had anything to do with the formation of the ring. In my case the membranes were intact and bulging well into the vagina, while in Cameron's case they had been ruptured for some hours. In the latter case, I think, the ring must have formed before the membranes ruptured, otherwise the head would have been pressed down into the brim of the pelvis, and the ring would have formed above it, as it usually does in labours obstructed by contracted pelvis, when the membranes have been ruptured for several hours.

Causes of the formation of the ring.—One cause which has been given is the use of dilating bags. In my case the largest Barnes's bag was used, but it was so quickly expelled that it is difficult to understand how it could have been the cause. I have used dilating bags scores of times without any such result. Another cause which has been given is the use of ergot. Undoubtedly, the hour-glass contraction of the uterus, which occurs occasionally during the third stage of labour, is generally due to the use of ergot. Hour-glass contraction of the uterus during the third stage of labour is caused by the retraction ring, and in one of the cases I shall shortly narrate I had a very typical example of it. In neither of the two cases was ergot used.

In the first stage of labour we occasionally meet with a spasmodic condition of the os, where the circular fibres round the os have not been inhibited, and these fibres contract along with the fibres in the main body of the uterus, so that the os actually gets smaller instead of larger with each uterine contraction. Now, there is a considerable resemblance between the circular fibres round the os and the fibres of the retraction ring, and what causes the spasm in the former may cause it in the latter. Spasmodic contraction of the os is generally supposed to be due to an irritant which acts reflexly. I make this suggestion, but I must confess it is not much of an explanation.

Diagnosis.—There is no apparent obstruction to the advance of the head, and yet the labour is delayed, although the uterine contractions are strong and frequent. The uterus may be in a tetanic condition without any relaxation between the pains. On palpating the abdomen you will find that the head is well above the brim of the pelvis, and you cannot push it down. If the abdominal wall is thin you can feel the ring, but with a thick wall you may not feel it. On making a vaginal examination you find the os dilated and the lower uterine segment opened up, but some three inches or so above the os you feel a distinct ledge running round a portion or the whole of the uterine cavity *in front of* the head. During a pain this ledge does not relax, but it becomes more prominent and prevents the advance of the head. The membranes may or may not be ruptured. If they are intact they protrude into the vagina, and they may even be seen at the vulva.

---

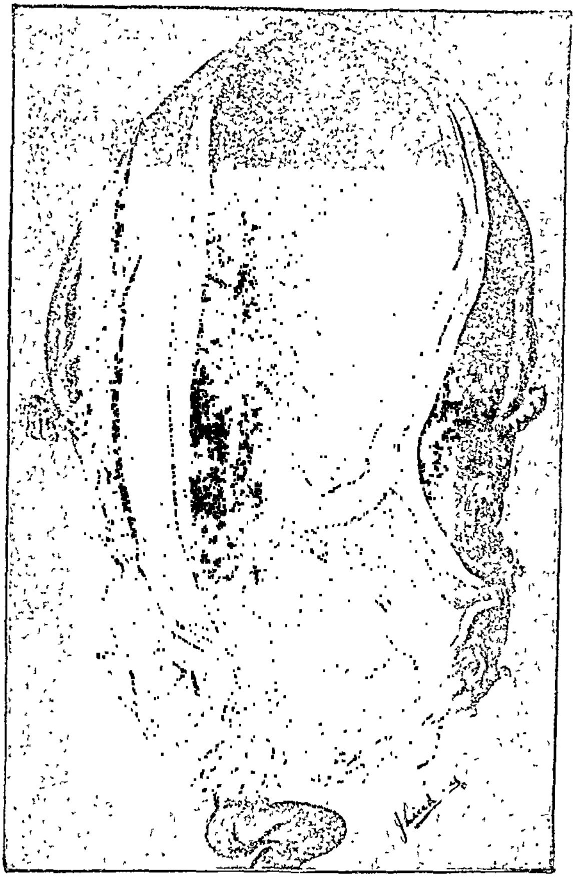
[1] A paper read at a meeting of the Edinburgh Obstetrical Society on May 14th, 1913.

Prognosis.—If the condition is recognised in time both mother and child should be saved; but, unfortunately, in many of the recorded cases a definite diagnosis was only made when exhaustion had set in, and there was little chance of saving either mother or child.

Treatment.—If the child is alive I am convinced that Cæsarean section is the proper treatment. Full doses of morphia or opium have been recommended, but I have never seen any effect in causing relaxation in a number of cases in which morphia has been used freely. Manual dilatation has also been advised, but the hand is powerless in such cases. Incision of the ring has been advised, but it would be impossible to prevent the incisions extending, and this would end in rupture of the uterus. Hydrostatic bags are useless, as you cannot introduce them high enough to bear upon the ring. If the child is dead it could be delivered by craniotomy, provided you have an instrument which will enable you to make powerful traction. If the shoulders are caught the clavicles should be cut.

2. *Cases in which the Retraction Ring Forms Above the Presenting Head.*

In these cases the membranes rupture before there is much dilatation of the os, or even before labour has begun. The first stage of labour is very prolonged, and by the time the os is fully dilated the ring has formed above the head round the neck of the child. There is no descent of the child, because the shoulders are obstructed by the ring. The case, from which the specimen I show was obtained (see figure), was probably of that nature, although it was a face presentation with the chin to the back. The pelvis was a very roomy one and there was no reason, so far as the pelvis was concerned, to prevent descent, even with the chin in a posterior position. However, I did not see this case until the patient was dying, so I cannot give the particulars in regard to the labour.



Rupture of the uterus showing the retraction ring. The posterior wall of the uterus is removed.

The following cases are typical examples of the condition:—

CASE 1.—The patient was a multipara with a roomy pelvis. Her previous labours had been easy ones. The membranes ruptured at

quite fully dilated, but full dilatation was easily effected manually. The head was high up in the first position, and not in any way

and I found that the head was above the brim of the pelvis, and there was no obstruction below it to prevent its descent, but on passing my hand above it I found the retraction ring was gripping the neck all round. I had never before seen such a complete ring. The finger tips could be pushed between the neck and the ring, but it was impossible to dilate it. I could not detect any fœtal heart sounds, but Dr. Holmes thought he had heard them shortly before my arrival. We discussed the propriety of doing Cæsarean section, but decided against it, as there seemed very little chance of savi

of the mother was not very favourable

axis traction forceps again, but they a

for some time. I then perforated the

instrument, which obtained such a po

was able to overcome the resistance of

There was no bleeding during the th

and suprapubic pressure failed to dislodge it. I passed my hand into the uterus and found that the placenta was separated, but it was gripped by the ring. It was a typical case of hour-glass contraction of the uterus during the third stage of labour. I removed the placenta and gave an intra-uterine douche. The patient was very exhausted, but with free stimulation and rectal saline injections she rallied and made a good recovery.

CASE 2.—I saw this case in consultation with Dr. T. C. Barras. The patient was a stout i-para with a very roomy pelvis. During her pregnancy she had suffered from an irritating vaginal discharge, which was treated by douching and swabbing out the canal. For several days before the actual onset of labour she had complained of pains which were evidently false ones, as no dilatation had occurred. When labour set in the membranes ruptured early, and the dilatation was very slow. After a good many hours the patient was becoming exhausted, so Dr. Barras decided to deliver her. The head was partly fixed in the brim of the pelvis, and on pushing it up to pass a catheter a gush of extremely foul liquor amnii came away. The odour was so bad that the anæsthetist suggested that surely the small intestine had given way.

I was called in, and found the head partly in the brim (L.O.A.), and it was not obstructed in any way. The stench from the liquor amnii was very overpowering. I emptied the bladder and applied Milne Murray's forceps, and with considerable difficulty got the head down, but not quite free of the vulva. The posterior vaginal wall and perineum gave way, but the sphincter ani remained intact. It was quite evident that the body was being obstructed, so I passed my hand up by the side of the head and found that the neck was tightly grasped all round by the retraction ring. The whole uterus had been pulled down, so the ring was about the level of the brim. I could get the tips of my fingers between the ring and the neck, but on trying to dilate the ring I could make no impression upon it, and my hand quickly became powerless. As the child was now dead, I passed a crotchet in and tore the right clavicle out, and removed the right arm. Even then the body would not come through, so I broke the clavicle of the other side, and by aking traction with the crotchet hooked into the chest, and pulling the head, the body was delivered. There was no great difficulty th the placenta. After douching and cleansing the parts I repaired e vagina and perineum.

The patient was very exhausted, but she soon rallied. She passed through a very stormy and prolonged puerperium, but ultimately recovered. Septic absorption occurred through the vagina, and she developed a pelvic abscess in the right side, which burst into the vagina. I dilated the sinus and evacuated large quantities of very foul-smelling pus on several occasions, but it was impossible to get free drainage even through a large vulcanite tube. Finally, openings had to be made in two places above Poupart's ligaments, in the right labium majus and in the thigh. An attempt was made to obtain a vaccine, but the bacteriologist reported that there was such an enormous growth of bacteria that he could not prepare one. The uterine cavity seemed to have escaped infection, as the discharges from it remained quite normal. The septic liquor amnii had nothing to do with the formation of the retraction ring. I have seen the same condition in several other cases, where the membranes had ruptured at the commencement of labour.

Causes.—The membranes rupture before there is any dilatation of the os, and the uterus soon gets moulded round the child. During the slow dilatation of the os retraction takes place, and the ring forms round the neck of the child; but there must be more in it than that, because we see many cases where the membranes rupture early, and many hours elapse before the os is fully dilated, and there is no obstruction to the advance of the body. There must be a determining cause, but it is difficult to say what it is.

Diagnosis.—If the patient is thin palpation will reveal the presence of the ring. Both of these patients were too stout to allow of this. An internal examination reveals that the head is high up, but it is not obstructed, and on passing your fingers beyond the head you feel the distinct ledge in front of the shoulders.

Prognosis.—If the condition is recognised early the chances for both mother and child should be good; but if it is only recognised after attempts to deliver have failed, then the prognosis is unfavourable, especially so for the child.

Treatment.—Opiates seem to have no effect in causing relaxation. In Case 1 several doses were given to assist the dilatation of the os, but this did not prevent the formation of the ring. Manual dilatation I have found useless. If the forceps will hold you may be able to drag the shoulders through, but in my second case I failed. When the child is alive undoubtedly the proper treatment is Cæsarean section. It will be necessary to divide the ring to allow extraction of the head, as occasionally has to be done in contracted pelves, where the membranes have been ruptured for some time and retraction has occurred. When the child is dead a crushing instrument which will take a powerful grip of the head, such as my combined instrument, will enable you to drag the shoulders through. Division of the clavicles will facilitate this. Version is of course contra-indicated.

3. *Cases in which the Retraction Ring Forms in Breech Presentations.*

When the legs are extended in a breech presentation impaction generally occurs. The breech comes into the brim, and there it sticks, although strong contractions are occurring. The usual explanation that is given is that the extended legs act as splints and prevent lateral flexion of the body. A splint should be rigid, and it should be firmly fastened if it is to prevent movement. I fail to see how the extended legs of a child fulfil these conditions. Not only are they hinged at the knees, but they are fairly flexible sideways, and they are only firmly fastened at the hip-joints. The upper end of the supposed splint is not firmly fixed.

When the legs are extended I believe that the true cause of the impaction is the retraction ring gripping the child behind the knees, so that its legs and feet are hitched above the ring. In these cases the membranes rupture early, and the whole of the liquor amnii drains away, and the uterus becomes moulded round the child. By the time the os is fully dilated the ring has become a very palpable ledge inside the uterine cavity, and with each uterine contraction it contracts and grips the child so firmly that descent is prevented. I have frequently demonstrated this to my residents in the hospital. In two instances in which I was called in consultation, after the attendants had failed to deliver by traction on the breech, both of the men told me that they had found a ledge inside the uterus which was causing the obstruction. In one of these cases the attendant had tried to deliver with a blunt hook, using all his strength, but had failed. When I delivered the child alive I found a large wound in its groin, which I had to stitch.

Diagnosis.—When the breech is impacted always suspect extension of the legs, and pass your hand in along the front of the child, and you will feel the ledge. You may be able to palpate it through the abdominal wall, but it can be recognised much earlier, and more easily, by an internal examination.

Prognosis.—The risks to the mother are very small if proper precautions are taken, and to the child they are not much greater than in an ordinary breech case which requires artificial delivery.

Treatment.—Traction upon the breech by forceps, fingers, fillets, &c., is of little use, and as for a blunt hook it should never be used on a live child. Have the patient deeply anæsthetised, then pass your flattened hand in carefully along the front of the child until you reach a foot, then sweep it inwards over the front of the child and bring it down. This must be done with care, as the lower uterine segment is thinned out, and if care is not taken it may be ruptured. When the leg is brought down make traction upon it, and get an assistant to keep up firm pressure upon the fundus of the uterus to prevent the arms going up and to keep the head well flexed. If the arms are caught they must be relieved by sweeping them over the front of the child, and the after-coming head must be dealt with in the usual way.

I do not think that sufficient attention has been paid to the retraction ring as a cause of obstruction in labour, and I trust the subject will be fully discussed. It is a rare complication of labour, but my experience shows me that it is commoner than is generally supposed. I have seen other cases than those I have mentioned; and in looking back I can recall a number of extremely difficult cases with which I have had to deal, which puzzled me at the time, but which I now recognise were cases of this kind.

Glasgow.

TUBERCULOSIS OF THE UTERUS.

BY J. W. THOMSON, M.A., M.B., C.M. ABERD.,
ASSISTANT SURGEON, WAKEFIELD GENERAL HOSPITAL.

TUBERCULOUS disease of the uterus may be primary or secondary, usually the latter, the source of infection being a tuberculous salpingitis; but the infection may also be conveyed by metastasis through the blood stream, or directly by coitus, as pointed out by Montgomery.[1] Tubercle bacilli have been found in the semen of phthisical patients. Those rare cases in which no other tuberculous focus is found constitute the primary form.

Three varieties may be described—the corporeal, the cervical, and the combined or cervico-corporeal form. The corporeal is the most common form and may be miliary or ulcerative, and is strictly confined to the body of the uterus, ending, it may be, abruptly at the internal os, as in Stewart's cases.[2] The disease may present the features of an ordinary endometritis, the true nature being only revealed on microscopic examination, or it may involve the musculature of the uterus in varying degrees. The cervical canal may be blocked, resulting in a tuberculous pyometra—the so-called uterine phthisis. Montgomery reports a case in which the disease was confined to the myometrium and had originated there, and was probably transmitted by the blood-vessels. The cervical variety is rarer and may be of the miliary, ulcerative or papillary form, resembling the venereal wart or early carcinoma, but is less friable than the latter, has less tendency to bleed, and there is free muco-purulent discharge. There may exist tuberculous disease elsewhere, and the microscope would decide. The cervico-corporeal form is of extreme rarity. The following is an example of the corporeal variety.

The patient, aged 20, had no family history of tuberculous disease. At the age of 13 an operation was performed for dysmenorrhœa. At the age of 18 several attacks of appendicitis were followed by the operation of appendectomy, which I am told was excessively difficult owing to pelvic adhesions. For two years fairly good health was enjoyed, after which she was again admitted to this hospital suffering from frequent, urgent and painful micturition. The dysuria soon subsided with appropriate treatment. A large amount of pus was present in the urine, which was acid and of normal quantity. No tubercle bacilli were discovered in it, but the bacillus coli abounded. Inoculated guinea-pigs died in a few hours From time to time the pus greatly diminished in amount or actually disappeared, and this was accompanied by pain in the abdomen and a rise in the temperature, which was at other times normal As a rule there was no pain or n Pirquet s test was negative much thickened right ureter ft ureter The uterus was fixed in the retroverted position Cystoscopy was difficult and no abnormal communication with the bladder was found *There were some tubercles round the right ureteric orifice* Neither kidney was palpably enlarged, and the amount of pus was too large to be derived from a kidney that was not easily palpable Accordingly, the abdomen was opened by a paramedian subumbilical incision

---

[1] Keen's Surgery, vol. vi.
[2] Glasgow Medical Journal, April, 1912.

To the left side of the retroverted uterus over an area of the size of a florin the bladder was densely adherent On separating these structures a communication was found to exist between them admitting the index finger, on the one hand into the bladder and on the other hand into the uterus The friable bladder wall was sutured with difficulty The pelvic colon running from right to left was firmly attached to the fundus of the uterus This was separated and the wall of the intestine repaired The uterus was with ease separated from the rectum the finger merely traversing soft granulation tissue, but leaving an aperture an inch in length in the rectal wall The lumen of the rectum was narrowed as in Jellet's case[3] (Periodic attacks of diarrhœa were recorded) The Fallopian tubes were hard, irregular, and thickened These were freed, and the uterus was now attached to the cervix by a narrow ragged pedicle, which was divided The uterine arteries were not encountered, being obliterated probably by a tuberculous endarteritis and finally disappearing The internal os was obliterated In sharp contrast to the condition of the body of the uterus was that of the cervix, whose peritoneal coat was intact, and it might at first sight have been mistaken for the sutured stump of a supravaginal hysterectomy It almost seemed as if an attempt was in progress by the serous membrane to entirely separate the healthy cervix from the tuberculous body—a serous line of demarcation A suprapubic drain was introduced

The interior of the uterus presented two abscess cavities, the one above mentioned Above this was a small section with normal lumen Above this, again, was another abscess lined with tuberculous granulation tissue and containing some calcareous particles The wall of the uterus showed much caseous material The left ovary was not found, the right was of normal size and consistence, and lay on the floor of the pelvis in what seemed to be a separate compartment of peritoneum, and was not disturbed Certainly on the surface of the right kidney, and I think also on the left, tuberculous nodules were felt due to ascending infection by the periureteral lymphatics[4] There were no tubercles on the peritoneum

Pus disappeared at once from the urine, a little albumin remained The expected fæcal fistula developed There was a slight gain in weight, and the patient left the hospital with a lessening fistula and is now undergoing special treatment

Histology—The following report is by Dr M J Stewart clinical pathologist, Leeds Infirmary "Three separate portions have been examined microscopically and all show the same appearance The myometrium is infiltrated by large masses of tuberculous granulation tissue composed of innumerable aggregated giant cell systems Some of the larger masses are the seat of central caseous necrosis but this is not a prominent feature The process is a fairly acute one, and there is little or no attempt at peripheral fibrosis The tubercles are quite characteristic and large well formed giant cells occur with great frequency The endometrium appears to be completely destroyed Examination of the tube (one only) shows that the mucosa is still intact and is the seat of numerous typical tubercles The lesion appears to be a recent one or there would be more destruction of mucous membrane Several sections have been stained by Ziehl-Neelsen s method but I can find no tubercle bacilli in the uterus In the tube, however, one of the giant cells contains a tubercle bacillus "

Remarks—Patel[5] states—

> Hysterectomy is only allowable when the disease is limited as in an adenomyomatous tumour of the uterus which has undergone tuberculous degeneration or a common fibroid or even a carcinoma which may undergo similar degeneration while when the tuberculous disease is more of the inflammatory than the neoplastic type constitutional and specific treatment is necessary surgery being dangerous When however the appendages are implicated the uterus should be removed entire with Fallopian tubes and ovaries subtotal hysterectomy being unsurgical

In the above case operative treatment was obviously indicated, and I am convinced that if a diagnosis had been effected at an earlier stage subtotal hysterectomy followed by vaccine therapy and the general treatment of tuberculosis there would have been excellent prospect of cure In cervical tuberculosis high amputation of the cervix or even curette or cautery may bring about a cure

Early diagnosis of the corporeal form, both as regards the existence and the extent of the disease, must be excessively difficult and of supreme importance Dr Jellett points out *that he has never found tuberculous disease of the uterus* that did not eventually lead to serious complications The development of these serious complications—such as implication and perforation of the bladder with resulting pyuria, involvement of the ureters and kidneys, severe hæmorrhage, recto vaginal fistula, &c—would lead to further investigation and elucidation of the case It must, however, be our endeavour to prevent these calamities If a tuberculous lesion is found elsewhere, and there also exists any pelvic trouble, it would be well to think of tuberculous disease of the uterus and employ energetic treatment We must remember, too, that, as in the case reported above, an attack of appendicitis may be the signal that all is not well in a tuberculous sense with the pelvic organs Hence those small incisions the practice of many, the boast of some, are to be much condemned for through these thorough examination of other organs is impossible In cases of endometritis, anyhow of obstinate endometritis, the uterine scrapings should be submitted to microscopic examination, and if found to be tuberculous extirpation must be practised to avert the final horrors of the disease

Wakefield

Reviews and Notices of Books.

A Text book of Midwifery for Students and Practitioners By R W JOHNSTONE, M A, M D Edin, F R C S Edin, M R C P Edin, *Assistant to the Professor of Midwifery and to the Lecturer on Gynæcology in the University of Edinburgh, &c* London Adam and Charles Black 1913 Pp 485 Price 10*s* 6*d* net

THIS book has been designed primarily to supply students with a text book of convenient size, but special attention has been given to practical points and to the management of normal and abnormal cases, so that it may also prove useful to practitioners The early chapters on the development of the ovum and placenta have already appeared in almost their present form in the author's "Outlines of Early Development" They are good and up to date are much simplified by the omission of all references to comparative embryology, and the description has not been carried beyond the organs that have a direct bearing upon obstetrics The book is of interest since it is to a large extent a *résumé* of the teaching of the Edinburgh School of Obstetrics, or perhaps it would be more correct to say that of Sir John Halliday Croom, to whom the work is dedicated

It is always disappointing to find in a manual of this kind small inaccuracies which could easily have been avoided For instance in discussing the height of the fundus of the uterus at the various months of pregnancy, on p 79 we are told that at the end of the fourth month of pregnancy the level of the fundus of the uterus—by this no doubt the author means the upper border of the fundus—is about two inches above the symphysis pubis In Fig 53 it is correctly shown at a point about opposite the fifth lumbar vertebra, of the calling of medicine now taken by all who think deeply on the subject makes any alteration in the material prospects of the medical practitioner. In our opinion all the indications are towards the enjoyment by the medical profession of a greater prestige and a fuller power of expansion in the time ahead of us. We believe that the ranks of medicine will be recruited in the near future by men of as high scientific promise as ever, and possibly the recruiting will be larger; and we believe also that the whole level of general practice will be raised by the association of all its practitioners in some orderly manner with the developments of any branch of any science whence medical contributions are required. We are aware both of the bitterness of the struggle through which medical practitioners have recently passed, and, moreover, that that struggle is not yet past; but the fact that the material damage done to the medical profession has been counterbalanced by certain recognised advantages will prevent any disastrous numerical deficiency in our ranks, while all the signs of the times encourage us to believe that the approaching years will find the exponents of our knowledge, craft, and art in leading positions in the councils of the nations.

Malingering under the National Insurance Act and Medical Referees.

THE dissatisfaction of the Friendly Societies with the financial situation brought about by their expenditure upon medical benefits since the National Insurance Act has been in force took the form of a resolution at the National Conference of Friendly Societies[1] that the administration of medical benefits under the Act should be transferred to the Approved Societies. Apart from a transfer, which we think will not, and which we are certain ought not, to take place, the appointment of medical referees is the principal remedy suggested for the checking of an evil which no doubt exists, and which must at any rate contribute to the expenditure due to sickness to an extent which the Friendly Societies regard as unnecessary. The amount of malingering in existence is in question, and it is difficult to see how we can know the extent of the evil until some steps to remedy it are taken. Undoubtedly the checking of malingering presents grave difficulties, and the fearless and intelligent use of medical referees should do something to control it, but that it will restore the expenditure upon sickness to a point satisfactory to the managing bodies of Friendly Societies is not to be anticipated. They have always stood for thrift, but in the past their most obvious economy was at the expense of members of the medical profession, and the attitude of their own members towards the medical attendance and medical benefit provided by the Insurance Act is now the cause of the drain upon their funds of which they complain. It is not the fault of the medical men upon the panels that patients seek their aid, but it would be surprising that they should do so if that aid, when given, were of the character recited in one of the motions before the National Conference of Friendly Societies. Reference to it will show that it assumed "an excessive expenditure on medical benefit and the inadequate and unsatisfactory service obtained therefor," but in the discussion which took place this view was not accepted unanimously, and Brother STANTON, of the Rechabites, made an awkwardly unanswerable point when he observed that "whilst delegates in conference were saying one thing, their members were running to the doctors as fast as their legs could carry them. It was not the members who were saying that the medical service was unsatisfactory, but the officers of the society, because it was costing so much in proportion to what it did before." Brother STANTON'S words should be seriously considered by advocates of the administration of medical benefits by Approved Societies, who utter vague threats as to their power to restore the old order through the weight of the votes at their back. It is by no means certain that the votes of their own members would support them in their desire to restore medical attendance to its former position under the Friendly Societies.

What amount of malingering exists, as we have said, is doubtful, but the employment of medical referees seems a necessary preliminary for dealing with the question. Malingering is a form of fraudulent imposture which legislation for the benefit of the working classes has already increased through the Workmen's Compensation Acts, and which honest working men must desire to see detected and, if possible, punished. It must be conceded by all that the position of a medical referee appointed with the admitted object of checking expenditure upon sickness under the Insurance Act will be one of difficulty and of responsibility, and one which will only be adequately filled by a medical man who has the confidence of members of his own profession on account of his undoubted qualifications for the post which he will occupy. In the performance of his duties he will have to smooth his own way as well as that of others by the exercise of tact, but he will have at the same time to be a strong man occupying a strong position. These considerations have the double significance which is so eternally embarrassing. They point to the advisability of the medical referee being a whole-time official, remunerated by a salary which will attract a good man to the post, and employed under conditions which will ensure the independence of his actions and decisions. But they point to the necessity of selecting only a man who has first-hand knowledge of the difficulties of practice among the poor, and who is also a sound and seasoned clinician. Even then too much must not be expected from the medical referees, particularly as regards financial results. Their salaries and expenses will absorb an appreciable part of the economies which they will effect, if those salaries and expenses are to be defrayed from the funds which it is desired to protect. The public value of the appointments will depend, firstly, upon ascertaining how far malingering, justly so called, is responsible for the expenditure complained of. The expenditure on ailments formerly untreated (which is in some quarters particularly resented in the case of women) is not due to "malingering," even though no medical treatment was sought before the Act. And, again, though malingering may probably be the cause of a great deal of unnecessary expenditure, it has yet to be ascertained that it can be brought so promptly and so generally to the notice of medical referees that they will be able to check it entirely, or almost entirely. Medical referees, moreover, will not be infallible in their judgments, any more than those medical men whose patients they may be called on to examine, and the temptation to malinger provided by the Act will remain as before.

A Women's Medical Service in India.

WE publish in another column the admirable address on the Medical Needs of India, which was delivered at the London School of Medicine for Women on the opening of the October session by Surgeon-General Sir Charles Pardey Lukis, Director-General of the Indian Medical Service. In the course of his address Sir Pardey Lukis, having dwelt upon the absolute necessity of the education of the Indian people in personal and domestic hygiene, as being the only way to lessen the dangers incidental to childbirth, to mitigate the horrors of a gross infantile mortality, and to remedy the sanitary defects owing to whose presence both plague and malaria are alike prevalent, comes to the essential fact that until the women of India are convinced as to the necessity of personal hygiene the root of all these evils cannot be reached. The only way at present of educating the people of India in the laws of personal hygiene is to rely on the magnificent efforts of the Indian Medical Service, of certain medical practitioners in India, of lecturers in association with the St. John Ambulance Association, and of missionaries. All these already discharge the duty of inculcating the principles of right sanitary living upon the populace, but unfortunately *purdah* intervenes, and only the male population of the empire can in this way be reached. Here Sir Pardey Lukis makes a significant statement, and one on which the whole of the scheme for a Women's Medical Service in India depends. He points out—and the information will be quite startling to many of us—that in the Indian home the wife and the mother are paramount authorities. So that, once let the women of the household be convinced that this, that, or the other proceeding is healthful and wise, reform will follow; but until this persuasion of the women can be achieved Sir Pardey Lukis thinks, speaking with an experience to which we willingly defer, that attempts to raise the standard of public health in India, to eradicate conditions leading to epidemic disasters, and to prevent the sacrifice of life now due to accidents of childbirth and infant mortality, will each and all be wasted to a considerable extent.

For the urgent needs of India at the present time an adequate supply of suitable and fully trained medical women is required, and Sir Pardey Lukis has exhibited to the London School of Medicine for Women the well-covered skeleton of a service designed to meet the existing position. The work both of missionary societies and of the Lady Dufferin Association, extraordinarily valuable and self-sacrificing as it has been, cannot pretend to cope with the conditions, and in particular the legitimate grievances of the medical women serving under the Lady Dufferin Association are admitted to require removal if recruiting for the association is to go on. The scheme outlined for a service to be called a Women's Medical Service in India shows in the first place careful provision for the selection of a small staff of 25 first-class medical women. Recruitment for the service will be made in two ways. In India a medical subcommittee of the Central Committee, including the Director-General of the Indian Medical Service, the surgeon to the Viceroy (who is *ex-officio* the honorary secretary to the Central Committee), and a first-class medical woman will select the candidates; in England a subcommittee consisting of a medical man and two medical women conversant with Indian conditions, to be nominated by the Home Committee of the Dufferin Association, will incur similar responsibility. In this way candidates will be properly examined for physical fitness, and it is provided that in the original constitution of the service duly qualified medical women who are already in the service of, or who have rendered approved service to, the Dufferin Association will have first claim to appointment; while thereafter special consideration will be paid to the claims of candidates who have qualified in local institutions and of those who are natives of India. The suggested terms of the new service are, we think, good. If it is objected that they do not err on the side of generosity, we have to remember two things: the first is that medical appointments, whether for men or for women, and whether at home or abroad, are seldom instituted on any but economical lines; the second is that the probationers of the new service will not be of any very great value to the scheme in its larger aspects during the early periods of their office. The whole service is instituted with the definite idea of getting into close touch with the domestic life of the native, and for this a knowledge of Indian ideas, standards, and traditions is absolutely required, and ability to converse adequately, if not fluently, in some of the languages of the country will be an advantage so extensive as to become almost a necessity. The terms of service are stated with considerable detail by Sir Pardey Lukis, and we refer our readers to them, but it will be seen that the salaries, which rise from R.350 per mensem to R.550 per mensem, will be supplemented by the provision of suitable quarters rent free, or by house rent in lieu, while travelling expenses at the usual rates can be drawn, and in addition to the usual privilege leave, eight months' furlough after four years' service will be granted, and study leave up to nine months. There will also be permission to engage in private practice so long as the performance of official duties is not encroached upon.

Lastly, there will be a provident fund as a provision for retirement. The rules of the provident fund are not yet formulated, but we are authorised to state that this fund will be contributed to separately from the pay of the members of the service, and not formed solely by deductions from salary. It may be taken for granted that whatever the members of the service put into the fund the Lady Dufferin Association will add an equal amount, and the whole will accumulate at compound interest until resignation. The proper amount of the contributions, the question of their forfeiture in cases of discharge for misconduct, the rates of interest and other details remain to be settled; but in the meantime we may point out that such a provident fund presents a flexibility that no pension scheme would possess. This fact is worth noting in the case of young women, who in the event of marriage would be able, with a short reasonable notice, to obtain their accumulated dues.

Annotations.

"Ne quid nimis."

PASSENGER SHIPS AND SMALL-POX.

THE Corporation of the City of London have recently drawn the attention of the Local Government Board to the risks of introduction of small-pox into this country through the Port of London. Many vessels arrive in the port within 14 days of their departure from ports at which small-pox is known or suspected to be occurring, and the corporation asked that the medical officers of health of port sanitary authorities should be empowered to inspect all persons on such vessels, to require them to give their names and addresses, and to detain on board any person whose address was considered unsatisfactory, suitable penalties being prescribed for non-compliance. The Local Government Board are reported to have replied that they did not consider, on the evidence before them, that they would be justified in adopting the course suggested, and the corporation in expressing regret at this decision have stated that in their opinion a serious loophole exists by which it is possible for small-pox to be introduced into this country. The possible introduction of small-pox in these circumstances cannot be denied, and the zeal of the City authorities, which is doubtless to be attributed to their apprehension of the results of the increasing neglect of vaccination, is to be commended. But it must be admitted that there are serious practical objections to their proposals. Although port medical officers of health cannot examine and detain passengers simply because the ship has come from a port in which small-pox is believed to be present, they can already offer vaccination and put in force measures of isolation and disinfection when the ship has had a case of small-pox on board or during the voyage, and they can also in these circumstances apply various other powers possessed by a medical officer of health on shore. But if the proposed new duties are to be added, and the work is to be done thoroughly, a large expense must be incurred in providing additional officers to undertake an irksome form of medical service, while the travelling public would be subjected to an amount of interference and inconvenience which ought not to be imposed without very strong evidence of necessity. Those who would put their main reliance on frontier action for keeping out small-pox would do well to study the recent experience of small-pox in Australia. In that country, where strict measures of exclusion are applied, the ports are few, the distances which have been travelled by the incoming vessels are long, and the conditions for securing defence by quarantine are almost ideal.

A PUBLIC HEALTH DISPUTE AT ARBROATH.

As a result of a considerable epidemic of scarlet fever in the town of Arbroath the hospital for infectious diseases became full, and the public health committee of the town council, in order to make some provision for the isolation and treatment of cases at their homes, decided to engage a visiting nurse or nurses who, when desired, were to undertake eucalyptus inunction and other proceedings adopted in what is known as the "Milne method." The medical officer of health, Dr. A. D. Yule, was instructed to circularise medical men in the district on the subject, but in the circular which he issued no reference was made to the "Milne method." His action in so doing was severely criticised at a meeting of the town council specially called to consider the matter, at which it was decided by large majorities that the intentions of the council should now be expressed to medical men and the public by the town clerk, and that the approval of the Local Government Board for Scotland should be asked to the nurse or nurses acting independently of the medical officer of health when requested by any medical practitioner in the town or by a guardian of a scarlet fever patient. A report in the *Dundee Advertiser*, from which our information is obtained, shows that Dr. Yule justified his refusal to carry out the wishes of the council on the grounds, first, that it was his duty to his medical friends not to attempt to impose any particular form of treatment on them; secondly, that the form of treatment to be offered was a medical question on which the town council had no right to dictate to him; and thirdly, that he was not willing to carry out the "Milne treatment" in Arbroath. The first of these arguments seems less strong than the other two. The public health committee does not seem to have wished him to do more than to supply facilities for treatment to such medical men as chose to avail themselves of them, and the committee may reasonably reply that medical officers of health make no such difficulties in other circumstances, such as the treatment of diphtheria by antitoxin, where facilities for treatment are afforded out of public funds. The root of the matter, however, seems to lie in the fact that the treatment which the committee desires to be supplied is one in the efficacy of which the medical officer of health disbelieves, and for which, on medical grounds, he feels unable to take responsibility. In these circumstances the town council has no more justification for objecting to his action than it would have if the town clerk advised that an agreement which it wished to make was illegal, or if its engineer reported that he considered the design of a bridge was unsafe. The views of the Local Government Board on the matter will be awaited with interest, and we would be surprised if that body were to give any decision which would discourage the expert officers of local authorities from fearlessly acting up to the opinions which they have formed, to the best of their ability, on the technical matters which fall within their province.

BOSSUET AS ANATOMIST AND PHYSIOLOGIST.

To the majority of our countrymen we fear that Bossuet is little more than a name, though most students of literature are probably acquainted with his Oraisons Funèbres as examples of "the grand style" in preaching, for which they were remarkable even in that century of sermons, the seventeenth. Few know, however, that amid the cares of the oversight of the diocese of Meaux he found time to write some 50 works chiefly dealing with philosophy, religion, the condition of the Church, and various controversial matters. One of his most noteworthy though little known treatises is that entitled "De la Connaissance de Dieu et de Soi-Même," written for the instruction of the Dauphin, afterwards Louis XV., an interesting critique and epitome of which has recently appeared from the pen of Dr. A.-F. Le Double of Tours.[1] The thesis which Bossuet set himself to defend was to show that the knowledge of God must be preceded by a knowledge of ourselves. To know ourselves we must grasp the fact that there are two parts in man, the soul and the body. These must first be considered singly and then as united.

---

[1] Bossuet, Anatomiste et Physiologiste. Par M. le Professeur A.-F. Le Double. Paris: Vigot Frères. 1913. Pp. 301. Price 5 francs.

From the consideration of soul and body we rise to the consideration of God, who is the cause and end of both. The treatise concludes with a chapter on the difference between man and beast. In his chapter on the body Bossuet gives a very fairly complete account of the anatomy and physiology of the different organs, though naturally the errors prevalent at the time appear in his descriptions. On the whole, however, the account is worthy of his teachers and friends, Duverney, Stenon, and Winslow. Dr. Le Double, despite his admiration for Bossuet's treatise, has no hesitation in pointing out the errors, and a large portion of his first chapter is devoted to them, and is illustrated by historical notes. The remainder of the work is mostly occupied by an examination of Bossuet's psycho-physiological views. As regards the general problem of his thesis Bossuet was naturally a teleologist; he says, for example, in his fourth chapter, "Whoever shall understand man will see that he is a work of noble design which could neither be conceived nor carried out other than by a profound intelligence." His end, says Dr. Le Double, was to reconcile dogma, reason, and science, to grasp the Infinite and the eternal by the study of the Finite and the mortal which come under the apprehension of the senses. Whether or no he attained the goal which he had set himself to reach matters little in his opinion. "Every effort of the mind towards the unknown, or even the unknowable, is praiseworthy, whatever may be the result. The beauty of the dream is none the less because unrealised; none the less are the nobility and usefulness of the emprise" Dr. Le Double's eloquent and instructive book should tempt many towards a further study of Bossuet's original work.

PREGNANCY AND CANCER OF THE CERVIX UTERI.

CARCINOMA of the cervix complicating pregnancy is naturally a somewhat rare disease, and its frequency has been estimated at about 1 case in 2000 cases of labour. When the conditions existing in an advanced case of this kind are taken into account it is not surprising that such cases are infrequent; indeed, it is strange that pregnancy should ever occur. As might be expected, the patients on the average are of a younger age than those in whom carcinoma alone is present, but that it may occur in a patient as old as 40 is shown by the interesting case of this kind recorded in THE LANCET of Sept. 27th, p. 930, by Mr. H. B. Mylvaganam. This case is particularly interesting because the uterus was the seat of a twin pregnancy, and evidently conception had taken place after the onset of the growth. The age of the fœtuses was probably 3 months, and there was a history of a blood-stained discharge extending over a period of some eight months with several hæmorrhages from the uterus during the last three months. When pregnancy does complicate the course of a case of carcinoma of the cervix, in about 30 per cent. of the cases premature expulsion of the ovum takes place, and in only some 40 per cent. is a living child born. If pregnancy proceeds to full term there are many accidents which may occur during labour. Extensive tears of the cervix are likely to ensue, possibly involving the bladder or rectum, and rupture of the uterus has been reported in a considerable number of the cases. Even if the patient escapes the immediate dangers of delivery her death from septic poisoning is a very likely sequel. In one curious case recorded by Menzies and mentioned by Cullen, missed labour occurred, the patient finally dying some 17 months after the commencement of the pregnancy; the fœtus was found to be in a condition of *fœtus compressus*, the liquor amnii having been absorbed, but showed no signs of maceration. As might be anticipated, a carcinomatous growth complicating pregnancy grows with great rapidity, no doubt as a result of the marked vascularity of the uterine tissues. In the operative treatment of these cases there is still some difference of opinion, not as to the advisability of immediate operation—most obstetricians are agreed as to that—but as to the best route by which to remove the uterus. Not many years ago the operation of choice in the early months, at any rate when the growth was removable, was vaginal hysterectomy. The immediate results were much better than those of abdominal hysterectomy, and the ultimate results recorded by Olshausen were remarkably good. At the present time, however, most operators, whether the pregnancy was in the early or the later months, would prefer to remove the uterus by the extended radical operation, and the same arguments which are adduced in favour of this operation would, of course, hold good with even greater force in a case of pregnancy complicating a carcinoma of the cervix. Obviously nothing is to be gained by a preliminary emptying of the uterus if the abdominal route is followed, and the loosening of the cellular tissues which is present during pregnancy and the ease with which the ureters can be isolated in these conditions is only counterbalanced by the extra vascularity of the tissues. Among the first 500 cases of carcinoma of the cervix operated upon by Wertheim by the extended abdominal operation there were 8 cases of pregnancy, including 1 of tubal pregnancy. Of these 5 were alive and free from any recurrence five years after the operation. One died from pulmonary embolism, and 2 had a recurrence of the growth. Mr. Mylvaganam is to be congratulated upon the successful result of his operation, and a record of the ultimate fate of the patient would be of much interest.

MEDICINE IN THE ITALIAN PARLIAMENT.

THE Third Italy (writes an Italian correspondent) is agitated by an impending general election—an ordeal trying to any old constitutional country, but peculiarly so to one whose "risorgimento" is comparatively recent, with the additional aggravation of an abrupt lowering of the suffrage to include every adult who can read and write. The polling, on a day not yet officially fixed, takes place in October, and many are the forecasts as to which of the numerous parties, or rather "chiesole" (cliques), into which Italy is divided, will emerge victorious. The anticipation preponderatingly held, however, seems to be that the astute Premier, Giolitti, will retain his working majority—master as he is of electioneering tactics in which the influence of the local prefect, ever loyal to the party in power, is a factor far from negligible. One feature of the contest already in progress is the greatly increased number of candidates drawn from the medical profession. Hitherto it has been the legal calling that has furnished the majority of aspirants to a Parliamentary career. Indeed, the "avvocati," or, as a sarcastic public is fain to call them, "avvocatucci," have outnumbered all other professions in seeking and obtaining the coveted distinction of deputy. But the country has become a little weary of these loquacious gentlemen of the toga, whose eloquence has hitherto proved expensive in the inverse ratio of their experience or knowledge of public interests. It is this that explains the really remarkable number of physicians and surgeons, in consultant or in general practice, who have entered the field, cognisant as they are of the country's real desiderata, which may be summed up in Disraeli's memorable watchword in 1874, "Sanitas sanitatum omnia sanitas." Significant in this sense is the fact that it is precisely in those regions of the kingdom where the sick-rate and mortality are highest, where popular superstition invariably rises in antagonism to hygienic law, particularly in view, or in presence, of epidemic visitation, where physical degeneracy is most pronounced, causing rejection of

40 per cent. at the periodical military levy, that the medical candidatures in question are most numerous and most actively promoted. Southern Italy, notably the Neapolitan provinces and Calabria, are the regions indicated, no fewer than five medical candidates courting as many of their constituencies. Some of these gentlemen hold university chairs, besides being in consultant practice, and the question arises, How can they possibly find time to do justice to their pupils or their patients, on the one hand, and to their constituents, on the other? The answer is that what would be next to impossible in England is quite possible in Italy, where attendance in the House is by no means so frequently required, so prolonged, or so exacting as in the Mother of Parliaments. The Chamber of Deputies in Rome does not commence business till late in the afternoon, seldom before 3 P.M., and its business is invariably over in what in England would be regarded as the early evening, between 6 and 7. As a matter of fact, there have been physicians and surgeons enough in the Italian Chamber who have combined the two rôles, that of practitioner and that of Parliamentarian, to justify each and all of the many medical candidates now before the constituencies in embarking on the twofold career. Lanza, a Piedmontese consultant, honourably refused all official salary as Prime Minister on the ground that his professional honoraria sufficed for all his wants, while he found time not only to earn the said honoraria, but to lead up to the events which brought his illustrious client King Victor Emanuel in 1870 to Rome. Guido Baccelli is another of the consultants who hold a university chair and a seat in Parliament with conspicuous efficiency in both capacities. The eminent patriot and sanitary reformer, Agostino Bertani, surgeon-general in Garibaldi's revolutionary force, is yet another exemplar of the compatibility of the medical with the political career; while as to the senators who have been promoted from the Lower to the Upper House while keeping in touch as teachers and practitioners with medical science and practice their name is legion. Italy, indeed, has everything to gain by the presence in her legislature of public-spirited consultants and practitioners, who, with no ambition for office, are yet prepared to give their thought and experience to the body politic, claiming as that body does, a serious, a systematic rehabilitation, in the sanitary sense, to which no Italian with any sense of citizenship can now remain indifferent.

DEFORMITY OBSERVED TEN YEARS AFTER AN ACCIDENT.

IN the *Australasian Medical Gazette* of June 21st Dr. Max Herz has reported a remarkable case in which deformity was not observed until many years after the injury which produced it. A boy, aged 15 years, discovered one day that his left hand did not run in the long axis of the forearm but had grown at an angle towards the thumb. On examination he was well built and healthy. The left wrist was in the position of manus valga, the hand forming an angle with the forearm opening on the radial side. There was no pain or discomfort or disability. The left forearm measured ¾ inch less than the right. A history of an accident 10 years before was obtained. During a game he jumped from the roof of a shed and fell on his left hand. The wrist became slightly swollen and was painful for a few days. A skiagram revealed the cause of the deformity. The outer side of the radial epiphyseal zone had ossified prematurely, retarding growth; the ulnar side had developed into a spur, the growth of which pushed the hand into a valgus position. A disturbance of growth with resulting deformity due to injury of one side of an epiphyseal zone is not uncommon. The peculiarity in this case is the interval of ten years between the injury and the observation of the deformity. Both the boy and his parents were persons of high intelligence.

DIABETES IN INFANCY.

IT is well recognised that diabetes may occur in infancy, even at the age of a few days, but the cases are very rare. Of 6496 fatal cases of diabetes which occurred in England and Wales in the decade 1861–1870 the age was under one year in only 8. The following case, which is recorded in the *Johns Hopkins Hospital Bulletin* for September by Dr. J. H. M. Knox, is therefore of interest. A highly strung nervous woman gave birth, after a normal labour, to a female child. Two years before she had a severe attack of jaundice. The father, though in good health, limped from healed tuberculosis of the hip. There were an elder sister, aged 4 years, in good health and a brother who died at 4 months from some gastro-intestinal disorder. There was no history of malignant disease, syphilis, or diabetes in the family. The child was breast-fed but also given diluted cows' milk. At four months she had a severe attack of bronchitis, during which the urine was found to contain pus cells, which disappeared under urotropin. Several examinations during the following months showed not a trace of sugar in the urine. At five months the child was put on a malt soup mixture for some digestive disturbance. She thrived for a time and rapidly gained in weight. She was first seen by Dr. Knox at the age of seven months, when she appeared to be perfectly well, but she was taking an unusually large amount of malt soup. This was discontinued, and a simple milk mixture, containing two-thirds milk and 4 per cent. dextrimaltose, was substituted. She did well for a month and then was seen on May 26th, 1912, because she was not gaining weight. She was bright but rather irritable. Her weight was 19¼ lb. On May 30th, at the age of 8 months, she was found to have a temperature of 101° F. and a fruity odour in the breath. The urine contained between 4 and 5 per cent. of glucose and acetone. On May 31st she was put on "eiweiss" milk. Her weight had fallen to 16 lb. and her temperature was 99·4°. Under this diet the sugar in the urine fell to 1·5 per cent., but the general condition was not satisfactory, and on June 7th she was admitted into the Johns Hopkins Hospital. She apparently tired of the "eiweiss" milk, and was put on a mixture of 32 per cent. cream, albumin, and water (the mixture having a composition of 3 per cent. fat, 4 per cent. sugar, and 2 per cent. proteid). The amount of sugar in the urine rose, and a week after admission she became drowsy and increased amounts of acetone and diacetic acid were found. Sodium bicarbonate was administered, but she became more and more drowsy, comatose, and died 11 days after admission, having shown signs of pulmonary involvement. The necropsy revealed broncho-pneumonia and cloudy swelling of viscera. The pancreas was of normal size and of an iron-grey colour. The lobules were homogeneous in appearance, and here and there were small spots, apparently islands of Langerhans. On microscopic examination the lobules were seen to be separated by rather broad septa. In the interstitial tissue were many small round cells, which in some places seemed to replace the acini. The connective tissue and the islands of Langerhans were diminished in size and number. The capsule was thickened. The diabetes, therefore, appeared to be of pancreatic origin. In this case it is noteworthy that thirst and appetite were not greatly increased and that polyuria was moderate. Dr. Knox has collected 16 recorded cases of diabetes in children under the age of one year (including his own). In 3 cases the disease was noticed within a few days of birth In half of the cases a statement was made as to the family history In 3 it was good throughout, in 3 a grandparent or great aunt had diabetes In 6 cases the disease seemed to have followed an injury to the nervous system In 2 of these the infants sustained a severe fall on the head In 2 other cases the symptoms may have been associated with injury at birth, as the labours were difficult In 3 cases there was increased cerebral pressure from hydrocephalus, and in 1 malformation of the brain (anencephalus) In 3 cases the disease began after the giving of an unusual amount of sugar One baby was fed on condensed milk, another was given 150 grammes of sugar and a litre of milk daily, and in the present case a litre of milk was given containing 10 per cent of malt infusion The majority of the cases showed the following symptoms in common At first restlessness was noticed This was followed by increased thirst hunger, and secretion of urine Loss of weight was a prominent symptom Multiple abscesses were present in 2 cases, gangrene of the lung in 1, and a sore over the sacrum in another At least 3 cases ended in coma Three of the patients recovered The majority of the more rapid cases terminated in three weeks The prognosis is grave but not hopeless, unless the condition is present in a severe form Treatment should be begun early and follow the lines of the treatment in adults The carbohydrate tolerance should be determined and the sugar-content of the diet correspondingly reduced An "oatmeal day" or days should be given at frequent intervals

THE SANITARY INSTRUCTION OF THE PUBLIC

ACCORDING to Dr James Kerr, whose report as the Medical Officer for Education of the London County Council was published in our columns on April 12th, schools play only a minor part under present conditions in the dissemination of infectious diseases Nevertheless, it must be recognised that children coming from infected homes are possible bearers of infection, even although they themselves may not be ill The desirability of complete coöperation of parents and teachers, as well as of the general profession, with the school medical officers, therefore, is undoubtedly to be desired But to attain this end the dissemination of knowledge is necessary, and in this we may learn something, perhaps, from Transatlantic methods The Department of Health of Chicago distributes weekly a circular leaflet entitled the *Bulletin of the Chicago School of Sanitary Instruction*, which deals with such sanitary and hygienic matters as are for the time being of pressing import the wording being brief, plain, forcible, and to the point, as is fitting in circulars intended for public reading In the *Bulletin* for August 30th now before us the approaching reopening of the schools after the summer vacation has directed the attention of the Health Department to the importance of safeguarding the health of the children against infectious diseases when they reassemble, and the advice given seems sane and sound The active assistance of all school principals and teachers is called for in the work of segregating possible infection bearers, and it is suggested that this should be the first and all important work of the first school day Principals are therefore recommended to see that, prior to the assembling of classes, the rooms are well aired, every window throughout the building being thrown wide open for hours before the children enter it Reference to the health department's records of contagious diseases, which are kept on file in Chicago in the office of every school principal is recommended, with a view to ascertaining whether any families from which pupils come have had recently reported cases of infectious disease It is further recommended that the teacher should carefully observe each child, and should order all suspicious cases at once to an isolation room or out of doors, to await inspection by the school doctor, all cases of sore throat, eruptions of any kind, desquamation, congested watery eyes, snuffles, visibly enlarged glands or coughs being reckoned as suspicious As an additional precaution, when the pupils have taken their seats, all those who now have, or have recently had, any sickness in their homes should be asked to stand up, when a little judicious questioning will probably make it clear whether any suspicion attaches to them as possibly coming from infected places The cooperation of the medical profession in immediately reporting all suspicious cases, and insisting upon strict isolation until absolutely sure that all danger of infection is past, is called for, while parents are urged to comply strictly with the requirements of the sanitary authority by never sending an ailing child to school or permitting even healthy children from an infected house to mingle with other children, inasmuch as, even though themselves well, they may carry infection to others "If," says the circular, "there be a proper measure of cooperation between the medical profession and the health department, there will be fewer small coffins to buy this fall and winter" Such circulars may indeed prove a fruitful source of public education in hygienic and sanitary matters, and in the last resort the people must be their own saviours in these matters, and to act intelligently it is essential that they should be instructed in what they ought to do The *Bulletin* does not in its instructions fit in with any possible routine in our schools, but the principles which it has in view are those upon which our system of school inspection relies

THE EMETIC ACTION OF DIGITALIS

MUCH of the recent research into the action of digitalis and allied bodies has been provoked by the fact that the emetic action of the former has appeared to constitute a serious obstacle to its continued use, and many have sought diligently for some preparation of the drug which might be innocent of those baneful effects, or for an alternative medicament possessing all the virtues of digitalis but none of its vices Most of these investigators have accepted without question the belief that digitalis is a gastric irritant, and therefore an emetic One of the most interesting and valuable of the data revealed by the researches of Dr R A Hatcher, of New York, and his colleagues was that experimental administration of the drug to animals by the intravenous method provoked vomiting, and that this effect of the drug was due to its action on the medulla, not to any direct irritation of the gastric mucosa One of Dr Hatcher's fellow workers, Dr Cory Eggleston, has investigated the same matter from a clinical standpoint Eleven cases of cardiac disease exhibiting auricular fibrillation, and four cases of chronic valvular disease with regular rhythm, received digitalis either as a tincture or as an infusion, and its emetic action was carefully studied with especial reference to its connexion with the cardiac effects of the drug (slowing of the pulse, alteration of the rhythm, and definite clinical improvement) Case records from the literature were examined along the same lines The result of these observations is remarkably uniform In 106 courses of digitalis treatment marked by nausea or vomiting there was clear evidence in 100, or 94 per cent, that the drug had been absorbed in quantities sufficient to produce a definite cardiac action before vomiting occurred Another fact which is strongly antagonistic to the gastric irritant theory is brought forward by Dr Eggleston, he quotes a number of cases in which very large single doses of digitalis (in one case 2 drachms of the tincture) were given without provoking any gastric symptoms whatever In view of these facts he argues that it is impossible to regard digitalis as emetic by virtue of an irritant action on the gastric mucosa; it is one of those drugs which cause vomiting by stimulation of the "vomiting centre" in the medulla. If general clinical experience should confirm this, it is a deduction of considerable importance; vomiting will be regarded not so much as an unfortunate check to the further administration of digitalis as an indication that the drug has been absorbed in adequate quantities. In the discussion which ensued upon the reading of Dr. Eggleston's paper at the Minneapolis annual meeting of the American Medical Association, Dr. Hatcher remarked that strophanthus is less emetic than digitalis for two reasons: first, it is less readily absorbed than the latter, and secondly, it possesses a smaller proportion of the emetic principle in relation to its cardiac activity.

THE RESEARCHES OF DANIEL HANBURY.

THE seventy-second session of the School of Pharmacy was inaugurated on Oct. 1st in the lecture theatre of the Pharmaceutical Society. The address was delivered by Dr. F. B. Power, Ph.D., LL.D., director of the Wellcome Research Laboratories, to whom during the proceedings Mr. E. White, President of the Pharmaceutical Society, who presided over the meeting, presented the Hanbury gold medal. Appropriately enough, Dr. Power chose as the theme of his discourse "The Influence and Development of Some of the Researches of Daniel Hanbury," for Hanbury was one of the earliest and most brilliant of the students of the school, and it is to perpetuate his memory that the medal is awarded biennially for high excellence in the prosecution and promotion of original research in the chemistry and natural history of drugs. The researches of Hanbury himself, as Dr. Power pointed out, did not include a great deal pertaining to the chemistry of drugs, but, on the other hand, historical and botanical studies had a special attraction for him, particularly in their bearing upon the history and source of drugs. The first communication made by Daniel Hanbury to the Pharmaceutical Society was entitled "On Turnsole," a product obtained from a plant indigenous to Southern Europe and the Orient. The expressed juice of this plant is at first of a dark green colour, but it speedily assumes a purple hue on exposure to the air; since Hanbury's investigations it has been shown that turnsole is used in Holland for the purpose of giving Dutch cheeses their characteristic red colour, and Dr. Power suggested that the chemistry of this product is a suitable subject for investigation, since it has been asserted that it possesses toxic properties. Other researches of Hanbury to which reference was made were those on the resin of the Norway spruce fir, on otto of rose, and on Chinese drugs. His contributions to Chinese materia medica were conducted 50 years ago and naturally involved very great difficulties on account of the little-known language and the limited facilities at that time for securing accurate information. Dr. Power made no reference to his own researches into the chemistry of drugs, the records of which form extremely valuable additions to pharmaceutical literature. He pointed out to the assembled students, however, that notwithstanding all the recorded facts and observations and the wonderful progress that had been made in recent years, the boundaries of science are constantly becoming enlarged, and with the broader view that is thus obtained the scope for effort and achievement expands. "The vast continents of Africa and Asia and the forests of South America, as well as the islands of the sea, doubtless contain among their natural resources," he said, "many thousands of plants which have never yet been touched by human hands, and a still larger number which have not as yet been named or classified. This wealth of material which Nature has provided will be sufficient to engage the attention of both the botanist and the chemist for a period of time so remotely distant that it cannot be forecast. There can, furthermore, be no doubt that the chemical study of the countless number of plants or plant products whose constituents are as yet completely unknown, will not only reveal much of scientific interest, but also principles of medicinal value which may be capable of alleviating some of the ills of mankind." The field of research is, in fact, practically unlimited, and the new Hanbury medallist is doing his share in the work of exploration.

THE HISTORICAL MEDICAL MUSEUM.

THE history of medicine is a subject which has of late years, in this country at any rate, attracted far more attention than formerly. The Royal Society of Medicine has organised a section of the History of Medicine, a section which held its first meeting on Nov. 20th, 1912, and in addition, also for the first time, a section in the same subject has formed part of the proceedings of the International Congress of Medicine which has just concluded its deliberations in London.

The history of medicine is a study of very many, and at first sight of widely divergent, matters, and the ideal medical historian would be a man of encyclopædic knowledge. He should know Greek, Latin, and Arabic, to mention only the three principal languages, as well as his own tongue. He should have a knowledge of palæography, be an accomplished physician and surgeon, have a knowledge of ecclesiastical history and the lives of the saints, and in addition be no stranger to anthropology and folklore; for the history of medicine is a part, and no mean part, of the history of human intellect and of search into the two great mysteries of life and death. Primitive medicine was, and is still among the few primitive races who are left, mainly concerned with amulets, charms, and incantations, i.e., songs. So in the Odyssey, when Odysseus's thigh had been ripped up by the boar, his father and brothers stanched the blood with a song, though with that practical wisdom which distinguishes the Homeric Greek they put a bandage on first:

> *ὠτειλὴν δ' Ὀδυσῆος ἀμύμονος ἀντιθέοιο*
> *δῆσαν ἐπισταμένως, ἐπαοιδῇ δ' αἷμα κελαινὸν*
> *ἔσχεθον* *Od. XIX. 456–8.*

Just as the study of medicine, surgery, and pathology is aided by the magnificent collection known to all as the Hunterian Museum, so a collection of articles bearing on the history of medicine is an aid to the study of that subject, and such a collection is now on view in London at 54A, Wigmore-street, a collection organised by Mr. Henry S. Wellcome and the result of some years' hard work. The museum was formally opened on June 24th, the proceedings commencing with an admirable address from Dr. Norman Moore, President of the Section of the History of Medicine in the International Congress, and attracted considerable attention from visitors to the International Medical Congress; indeed, the visitors' book would be an enviable possession for a medical autograph hunter. We have already given a short account of some of the exhibits in our issue of July 5th, but the field covered by the exhibition is so wide that we think it well to speak at greater length concerning some of the more interesting and somewhat recondite exhibits than was possible in the former article. Primitive medicine is well represented in the entrance hall by a collection of charms, fetishes, and professional dresses of medicine men from Africa. Here also are a very interesting collection of skulls showing early and prehistoric trephining. The peculiar characters of the trephine holes are noticeable for comparison with results in another case obtained by Dr. T. Wilson Parry, who trephined a number of modern skulls with prehistoric flint instruments. The correspondence of the results in the two cases is striking. There are also specimens showing the large percentage of bone disease and the prevalence of gall-stones and other

The Hall of Statuary: Oriental, Egyptian, Greek and Roman deities of healing, votive offerings, surgical instruments, &c.

conditions among the remains found in a prehistoric Ethiopian burying ground now being excavated for Mr. Wellcome at Gebel Moya in the Sudan, as well as the method adopted for preserving the specimens.

In the central hall or Hall of Statuary (Fig. 3) are statues of deities of healing such as Ixlilton, the Mexican god of healing, Apollo, Æsculapius, Hygeia and Cheiron for Greece, Shen-Nung of China, Dhanwantari of India, Ed, Gula, Adapa and Marduk of Chaldea and Babylonia, and Thoth, I-em-Hotep and Ptah of Egypt. On the staircase leading to the gallery are three pictures of St. Luke, St. Cosmas, and St. Damian respectively. These saints are three of those connected with medicine, and tradition has it were all medical men, the first being the subject of a most interesting paper read by Miss M. Stawell at the Congress, upon which we commented in our issue of August 16th. The two latter saints are not so well known, for they were in the main Eastern saints, though as patrons of the great Medici family they obtained a certain vogue in Florence, where they are represented in numberless pictures in their doctorial robes. It is said that the medical year beginning on Oct. 1st has its origin in the fact that that is their feast day. Other saints connected with medicine and invoked especially against the plague were St. Roche and St. Sebastian, the latter being specially venerated in Umbria and Tuscany, the former in Venice. All round the gallery are hung a series of water-colour copies of illustrations from manuscripts dating from the fifth to the seventeenth century, and in the gallery itself are cases containing charms and amulets, many of them collected in the East-End of London or in country places in our own day. Belief in charms is by no means extinct even among educated persons in the present day. Thus, as Dr. Norman Moore mentioned in his address at the opening of the museum, he once met a lady who carried a potato in her pocket as a cure for rheumatism, and we ourselves have had a similar experience, only in that instance the complaint was neuritis.

In the central hall also are cases showing surgical and obstetrical instruments, Oriental, African, and Græco-Roman; and the probable source of inspiration of the speculum now known as Ferguson's is shown in a case which presents one of these instruments in juxtaposition with a speculum constructed, according to a description in the Talmud, from bamboo, and another formed from the stem and lower part of a gourd. The origin of the term speculum, which really means a mirror, is suggested in a drawing from a Flemish print of the sixteenth century, in which the method of examination of the internal passages is shown. A medical cleric is seated with his back to a woman in whom a three-bladed dilator (of which several specimens are shown) has been introduced into the anus. He holds a mirror (speculum) high up in front of him to catch over his shoulder the reflection of the rectum thus opened up. It is possible that reasons of propriety suggested this use of the mirror in place of direct inspection, and that when the mirror was discarded the name speculum was transferred to the dilator itself. This method of inspection by mirror and dilator is mentioned in a MS. by Bernard de Gordon (1301) and by Avicenna.

The illustrations from manuscripts are a most valuable and instructive series, and we should much like to see them reproduced on a smaller scale and published as a collection in book form, for they represent a scattered treasury of information that is mostly otherwise inaccessible. There are delightful pictures of the collection of mandrakes, of surgical operations, of scenes in hospital, of botanical drawings, from Dioscorides and ancient herbals, of St. Apollonia being tortured by having her teeth pulled out, of birth scenes of the Cæsarean operation, of physicians and nurses, of post-mortem examinations, and many others. One picture of great interest shows the Emperor Valerius, as he is called in the catalogue, but who is better known as Maximin Daza, being eaten by worms. This picture is numbered 45, and we fancy that No. 291, which is described in the catalogue as "King Suffering from a Parasitic Disease" is really another picture of Maximin, though it might be the Herod who suffered the same or a similar fate. Another Emperor, Galerius, traditionally died in the same manner. Those anxious to know more of this subject will find it treated at length in Dr. Richard Mead's "Medica Sacra" under the title of The Disease of King Herod.

Another section of the museum is devoted to pictures and engravings of medical scenes and to portraits and busts of medical men, prominent among which is a magnificent series of portraits of Harvey, in addition to a copy of his bust as it stands upon his tomb in Hempstead Church, Essex. These copies were made to the order of the late Sir George Paget, and the one in the museum is lent by Mr. C. E. Paget. In the alcove is another equally interesting collection of portraits and relics of Jenner.

In the next room is a collection of MSS. and early printed books relating to medicine and surgery. A number of these were printed in English about the time of Queen Elizabeth, and deal mainly with surgery, for physicians at that period almost invariably wrote in Latin, and had, as a rule, a far better general education than surgeons. Some surgeons, however, knew Latin, for the author of a book called the "Key to Unknown Knowledge, or a Shop of Fine Windows," printed in 1599, deals in his first chapter with the judgment of urines, and says in a preliminary note that he has gathered together rules for the judgment of urine from divers authors for the benefit of his fellow chirurgians "which have not the Latine tongue."

Among the ancient MSS. of special interest are: Livre de Medécine d'Histoire Naturelle, by Huges de Salve, in French, dated 1390; MS. on Astrology, in Latin, Canones Super Tabulas, author unknown, dated 1296; MS. Inventory of the Hospital of St. John of Florence, dated 1397 to 1427; MS. Antidotarium, and other treatises, by Nicolaus Praepositus, in Latin, thirteenth and fourteenth centuries; MS. De Arte Medicine, with Ysagoge Johannicii, in Latin, fourteenth century; MS. Chirurgia, by Guglielmo di Saliceto, in Italian, fourteenth century; MS. A Treatis of Urines and Medicynes, in English, dated 1320. Among the more important Incunabula are: Practica de Medicinis, by Johannes Mesue, first edition, 1471; De Fructibus Vescendis, by Baptista Massa de Agenta, ca. 1471; Tractatus de Arte Cognoscendi Venena, by Arnoldus de Villanova, ca. 1473; De Medicina, by Cornelius Celsus, first edition, 1478; Tractatus de Regimine Sanitatis, Dominicus de Lapide, 1477; Liber Canonis, Gerard of Cremona, 1479; Herbarius zu Teutsch, Augsburg, 1496, the first German Herbal; De Morbo quem Gallicus vocatur, Coradinus Gilmus, 1497 (probably the earliest printed book on syphilis).

Here, also, in a glass show-case are an interesting collection of curious anatomical manikins, 15 in number, carved out of ivory, and showing the internal organs, the fœtus in utero, &c., in removable parts, which were probably used for instruction in midwifery in the fifteenth and sixteenth centuries; while in the basement below is a leather female manikin with dilated vulva and movable model of the fœtus and placenta, used in the seventeenth century for demonstrating the process of parturition to students in the old Hospital Pistoia.

In a gallery are a number of diplomas. Many of these from Italian Universities are beautifully illuminated. Harvey, it will be remembered, graduated at Padua, and a facsimile of his diploma was published in 1908 by the Royal College of Physicians. A copy of this facsimile is exhibited together with the portraits of Harvey. It was fully described in our columns at the time of publication. Among the diplomas may be specially referred to those granted to Joseph Serra in 1734 by the Medical College of Bologna, to Bernado José de Cavalho in 1777 by Mary, Queen of Portugal, to William Forester in 1608 by the University of Caen, and to Francis Henry in 1655 by the University of Montpelier. In the same section are a fifteenth-century Italian manuscript document referring to a miraculous cure of pestilence which occurred in Venice in 1464, and a free pass in time of pestilence issued in 1713 at Riana, Tuscany, the only one known to be in existence. Another very interesting exhibit in this section is a facsimile Greek Drug Order of the first century, warning the vendor against selling stale or adulterated drugs. A demand from the rector and council of the University of Pavia to the Inquisitor of Witches, asking him to deliver for anatomical purposes the body of a woman who had been sentenced to be burnt alive indicates the pressure in the early sixteenth century in the problem of the supply of anatomical subjects.

The basement of the museum is mainly devoted to pharmacy. There is a reconstruction of John Bell's shop as many of us can remember it in Oxford-street. Bell was the founder of the Pharmaceutical Society, and the shop was built in 1798. Another reconstruction shows a seventeenth century apothecary's shop which used to stand in the Old Bailey, and yet another, an alchemist's laboratory, *circa* sixteenth century, with original apparatus; also reconstructions of a barber-surgeon's shop (Fig. 1) and an accouchement room (Fig. 2), both of the sixteenth century, and of a Roman surgery in Pompeii. In this room also is a very fine collection of Italian and Flemish drug jars. Further along is a section devoted to nursing, with a number of portraits of Florence Nightingale.

We have reserved to the last some exhibits illustrating the more recent history of medicine. In the entrance hall is a collection illustrative of the progress of research in a matter that of late years has come greatly to the front—viz., pellagra. Dr. L. Sambon's theory is that the disease is due to the bite of the female simulium fly, of which insect specimens, both male and female, are shown under the microscope. Charts of regions where pellagra is endemic are shown, indicating that the distribution of the disease in all countries follows the course of swift-running streams in the high lands midway between the plains and the mountains. The distribution is, in fact, inverse to that of malaria, for the anopheles lays its eggs in the stagnant waters of the lowlands, while the simulium finds its most favourable environment for development in the rippling streams and freshets. The simulia have only a brief life in the torrential streams of the mountains, and are scarcely found in the sluggish streams of the low-lying lands. There is also a seasonal prevalence of the fly in the spring when freshets are abundant. This proof of the correspondence of the distribution of the disease with that of the simulium is displayed in charts of the Provinces of Urbino, Pavia, Brescia, Udine, and Venezia in Italy, as well as in charts of Northern Italy, Roumania, the Tyrol, and particularly the province of Bucharest. The outstanding fact in the province of Bucharest particularly is that the peasants live under similar conditions, including the use of the same maize diet in both districts; yet those in the plains are free from pellagra, while the disease abounds in the hilly districts where simulia are abundant. There are also coloured plates of the recent cases in England and pictures showing that the places where these cases have been found are similar in character to those in other lands where the disease is endemic. Further, there is a tube containing simulium larvæ found at Catford.

We have by no means exhausted the contents of this museum, the organisation of which must have involved an immense amount of enthusiasm and hard work, but Mr. Wellcome deserves the thanks of the whole medical profession, not only for having collected all the objects which he has (and in this matter we must associate Mr. C. J. S. Thompson who has arranged them), but also for his intention of making the present museum the foundation of a permanent historical medical museum in London. The museum will close this year on Oct. 31st, but we are informed that it will be reopened as a permanent museum some time in 1914. During October the museum will be open from 10 A.M. to 6 P.M. daily, and from 10 A.M. to 1 P.M. on Saturdays.

THE INTERNATIONAL CONGRESS OF PHARMACY.

SINCE the Tenth International Congress of Pharmacy was held in Brussels in 1910,[1] a permanent International Pharmaceutical Federation has been established, with the result that the eleventh congress, which was organised by the Federation and held at the Hague during the third week in September this year, was the most successful of the whole series. It was truly representative in character, since it was attended by delegates of 18 different nationalities. The British representatives were Mr. Edmund White, President of the Pharmaceutical Society, who was the delegate of the British Government; Mr. W. J. U. Woolcock, secretary of the Pharmaceutical Society; Professor H. G. Greenish, joint editor of the British Pharmacopœia; Mr. E. S. Peck, and Mr. H. Finnemore. The delegate from the United States was Professor J. P. Remington, editor of the United States Pharmacopœia, while many other countries sent their most distinguished pharmaceutical professors. The President was Professor L. van Itallie of the University of Leyden.

Proposed International Pharmacopœial Bureau.—Unification of Nomenclature.

As is usually the case with international meetings the papers were very numerous, and time did not permit of the adequate discussion of the majority of them. The most important subject from the international point of view was the proposal to establish an international pharmacopœial bureau for the purpose of examining, abstracting, and sifting all literature relating to pharmacopœial work. As so many of the delegates are members of the revision committees of their national pharmacopœias the matter was discussed with much earnestness, and it was decided to appoint a commission of seven members to consider whether the formation of such a bureau is desirable, and to report to the federation; the British representative on the commission is Professor Greenish and the American Professor Remington. Should the bureau be formed not only would the work of revision committees be simplified, but each national pharmacopœia committee would profit by the experiences of all the others. It is, therefore, to be hoped that the commission will see its way to reporting favourably on the proposal. Another subject of discussion well suited to the purpose of an international meeting was that of the unification of pharmaceutical nomenclature. The general opinion was that a universal nomenclature was desirable, and it was left to the federation to consider the matter in detail. M. C. Rousseau, who brought the proposal forward, suggested that in pharmacopœias an international name should be printed in brackets after the national name, and that where Latin words were not employed the international name should be in Esperanto.

Trade Marks, Synthesis of Glucosides, &c.

The application of trade marks to chemical products used in medicine was the subject of another interesting discussion. The president of the Pharmaceutical Society, who made a valuable contribution to the discussion, suggested among other things that brand names should not be applied to substances which were not originated by the owners of the trade marks. The Congress passed a resolution embodying the recommendation that every medicinal substance bearing a trade mark name should also bear an ordinary name from the use of which the owner of the trade mark would suffer no loss of rights. A lecture on the Synthesis of Glucosides by means of Ferments by Professor Bourquelot of Paris was probably the most important feature of the Congress. Professor Bourquelot is the most eminent worker in this special field of research, and he and his collaborators have succeeded in synthesising many glucosides by means of enzymes. He gave a most interesting account of his work, and made, for the first time, the extremely important announcement that he had recently discovered that the action of enzymes is synthetic as well as analytical. Up to a point the action of a ferment is to break up a glucoside, but at this point the synthetic action begins. The decomposing process ceases when a certain proportion of the product of decomposition is present. Hitherto it has been supposed that the action of ferments is a decomposing one only, and this discovery opens up a new field of research. Professor Tschirch, of Berne, another distinguished research chemist, gave an address on the Importance of Enzymes in Pharmacognosy; he drew attention to the fact that parts of living plants change considerably after they have been removed from the plant, and showed that these changes are in some cases due to enzyme action and are preventable by the destruction of the enzyme. Whether or not the changes are beneficial depends upon the purpose for which the drug is intended, and in view of this consideration Professor Tschirch discussed the question of the advisability of sterilising fresh vegetable substances used in medicine. The value of the cinematograph in pharmaceutical lectures was demonstrated by Professor Wijsman, of Utrecht, whose paper on the Cultivation of Drugs in the Dutch Colonies was illustrated by moving pictures showing how cinchona bark is cultivated in Java. The next congress is to be held in Berne in 1915.

A GERMAN GIFT FOR THE PURCHASE OF RADIUM.—A Würtemberg manufacturer has given to the Ministry of Education the sum of 50,000 marks (£2500) for the purchase of radium and mesothorium.

LOCAL GOVERNMENT BOARD FOR IRELAND:- ANNUAL REPORT FOR 1912-13.

THE forty-first annual report of the Irish Local Government Board has just reached us. It relates to the Board's proceedings during the year ending Lady Day, 1913, and contains evidence of satisfactory progress in sanitary administration in that division of the United Kingdom. From a medical standpoint it is important to note that sanitary operations in Ireland are regulated by a staff of medical inspectors, to each of whom is committed the charge of a definite area of the country. The reports of these officers form the source from which the present summary is derived. Particulars of the mortality from various causes in Ireland are cited from the report of the Registrar-General, to which reference has already been made in THE LANCET.[1] At the period covered by this report the provisions of the Infectious Diseases (Notification) Act had been adopted in 145 rural and 86 urban districts. In the first-named areas 3082 and in the last-named 6196 cases of infectious diseases were notified in the course of the year.

Typhus Fever.

Happily, this pestilence occurs rarely in England, and few of the rising generation of medical practitioners have ever seen a case. But in several parts of Ireland it seems to be practically endemic. In the year under notice 126 cases of typhus were notified in Ireland, but this number by no means represents the total incidence of the disease—partly because notification is not yet universally compulsory, but more especially because of the notorious fact that the initial cases of outbreaks frequently escape recognition. None of the outbreaks assumed alarming proportions last year, but a considerable number of attacks were reported from Galway and Dublin. Dr. Brian O'Brien gives an account of an epidemic visitation of typhus fever of an atypical character in the Stranorlar rural district, the origin of which was traced with much probability to infection conveyed in second-hand clothes. The Board refer with regret to the death of Mr. E. L. Aherin from typhus contracted in the course of his official duties in the Newcastle Dispensary district. In the county borough of Cork, where the disease has been of frequent occurrence in past years, only one case of typhus occurred in the period under review. Belfast also is stated to have been free from this fever.

Enteric Fever.

Throughout Ireland a gratifying reduction is reported in the incidence of enteric fever last year, when the number of notified cases was the lowest on record. Dr. T. J. Browne, the district medical inspector, reports that in Dublin the notifications were less than half as numerous as in the preceding year. Sir J. Acheson McCullagh, medical inspector for the Oughterard rural district, reports that enteric fever is more or less endemic in that locality. The water-supply is bad, mainly from wells, or rather holes in the field, and is liable to pollution in every form. The housing conditions also are insanitary. The fever in these cases was not of a pronounced type as regards the characteristics either of typhus or of enteric fever. "It was more of the 'mongrel type,' which is found so often on the western seaboard."

Tuberculosis.

Commenting on the circumstance that hitherto the notification of tuberculosis, under the Act of 1908, has been adopted in 41 districts only, the Local Government Board express the hope that before long steps will be taken to make notification compulsory, at any rate in all large urban districts. This is especially necessary as regards the boroughs of Cork and Waterford, where the incidence of phthisis is particularly heavy. In Dublin and in Belfast the notifications fall short of the recorded deaths from pulmonary tuberculosis; they cannot, therefore, be regarded as even an approximate index of the prevalence of the disease. In the interest alike of the patients themselves and of the community, the Board insist on the importance of securing notification of attacks before the disease has reached an advanced stage, and they impress upon sanitary authorities the necessity of acting on this principle.

The Board show considerable energy in supporting measures for the detection, prevention, and treatment of tuberculosis. Particulars are given of the progress already achieved, and of the advice and assistance rendered by the Board's expert advisers to local authorities who are responsible under the Tuberculosis Prevention Act.

The reports of the Board's medical inspectors contain accounts of their action in regard to the sanitation of their districts, together with statistics of diseases prevalent, and of the steps locally taken for its prevention. To these reports the attention of those interested in the health and well-being of Ireland may usefully be directed.

---

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Borough of Leicester.—The information given by Dr. C. K. Millard in his last report shows that the year 1912 was notable in various ways in the sanitary history of Leicester. The great Derwent Valley water undertaking was completed, and this source of supply was made available in September. The water is soft and organically pure, but has a brownish colour, due to its peaty origin, which at first was very pronounced. At present the new supply is being used in conjunction with the old service obtained from Charnwood Forest. During the year "sanatorium benefit" came into operation, and owing to the borough being already comparatively well equipped for the purpose, not only in respect of hospital accommodation but also by means of the tuberculosis dispensary which had been established in 1911, little difficulty was experienced in administering it. In order that the medical officer of health might act as administrative tuberculosis officer and medical adviser to the Insurance Committee a new arrangement was made by which the posts of medical officer and public analyst have been dissociated. Another noteworthy feature of the year was the virtual non-appearance of an autumnal diarrhœa epidemic. In past years these epidemics were a conspicuous feature of Leicester, which had the reputation of being a "diarrhœa town"; since the period 1898 to 1902, in which over 5000 pail closets were converted into water-closets, and other efforts made on a large scale to secure cleanly surroundings of dwellings, these annual outbreaks have been of much less intensity. The five years 1894-98 had an average diarrhœa mortality rate per 1000 births of 50·6; in the next five years 1899-1903 the rate was 39·7, for 1904-08 it was 34·5, and in the four years 1909-12 it has been as low as 18·7. In 1912 itself, a year meteorologically unfavourable to diarrhœa prevalence, the rate was only 6·5. The rate of infantile mortality from all causes has shown a corresponding decline, and it is noteworthy that this has taken place in a town which has not adopted the system of compulsory notification of births. It is possible that the objection to the latter measure may in part result from the high proportion of illegitimate births in Leicester; for 1912 such births were 5 1 per cent. of the whole. The municipal infants' milk depôt, unlike those in some other cities, has prospered. It is increasingly used, and is now said to be paying its way. Dried milk is exclusively used, the prices charged during the summer per pound being 1*s.* for full cream milk, 10*d* for "three-quarters cream," and 9*d.* for half cream. Reduced charges have been made in special cases, while the payments for the milk in some instances have been made by the Charity Organisation Society and by the Leicester guardians. The number of infants taken on the books, for longer or shorter periods, was 898 during the year. Infant consultations are held in connexion with the work of the depôt. About half the births in Leicester are computed to be attended by certified midwives, of whom there are 29. Dr. Millard does not consider the number to be inadequate. Some of the Leicester midwives are said to attend 150 or even more confinements a year. A small outbreak of enteric fever during August was traced to the consumption of a particular batch of ice cream, made on premises on which an ambulant case of the disease was at work. Appended to the report are a number of useful statistical tables relating to infectious diseases, hospital treatment, and other matters. We are glad to note that Leicester is taking part in the investigations of atmospheric pollution which are being made by the committee, of which Dr. W. N. Shaw, of the Meteorological Office, is chairman.[1]

County of Ross and Cromarty.—Dr. William Bruce gives an interesting report on the conditions which obtain in the scattered communities in this large area of the Highlands and in the Island of Lewis. He lays particular stress on the value of the school as a means of hygienic teaching, which he considers is not sufficiently utilised. He urges also, in the interests of growing children, that they should be allowed a respite from mental work as far as possible about the age of 12, and commends the old system of the children going to school in winter and being set free during the summer months, an arrangement to which, it is understood, the Scottish Education Department is not unfavourable. To make this plan successful, however, it would, of course, be necessary to extend the present age of compulsory attendance. The county possesses a sanatorium for early cases of tuberculosis, established by private munificence. The limited experience of notification of pulmonary tuberculosis suggests that about 200 cases will in future have to be dealt with in the whole county. Of these perhaps 100 will be cases on the mainland, and Dr. Bruce computes that here hospital accommodation would be required for at least 20. The bulk of the treatment of tuberculosis must be carried out at the homes, and for this purpose the prospect of the establishment of a satisfactory system of parish nursing, held out by the report of the recent Committee on the Medical Services of the Highlands and Islands, is greatly welcomed. The essence of sanitary improvement in many parts of this district lies in the solution of the housing problem, and Dr. Bruce urges that although the outlay of better houses may for the time being be unremunerative, it cannot fail to give ultimately an invaluable return. The Island of Lewis furnishes nearly 26,000 of the total inhabitants of the country who are estimated at 61,751, and special prominence is given to the report made on this area by Dr. D. Murray of Stornoway. In recent years a great deal of public attention has been given to the insanitary conditions of Lewis, but it is satisfactory to find evidence that considerable activity in sanitary work is now taking place. There is a considerable demand for new houses, while the objections to the "black houses" of the old type have been so much insisted upon that many of the islanders consider it useless to attempt any improvement of their older dwellings, and prefer to wait for new houses. The "black houses" in question are those in which the dwelling and the byre are under a single roof, with a vitiated atmosphere, and interiors that are damp, smoky, and sunless. Dr. Murray urges that those who are able to make a complete separation between the dwelling and the byre should at once be forced to do so. There is a hospital at Stornoway, but it is reported to be too far removed from many parts of the districts to be of much practical value. The record of the island for infectious diseases during the year appears to have been favourable; only three cases of enteric fever occurred, and an outbreak which followed importation of measles from the mainland was promptly checked. On previous occasions a very serious mortality from measles has resulted from its introduction in this way. The death-rate from all causes during the year was 13·56 per 1000 of the population, and the infantile mortality was distinctly low, not exceeding 49 per 1000 births.

The Island of Guernsey.—The population of this island is now estimated at 41,854, and in 1912 the natural increase of births over deaths was 431. Emigration is, however, actively going on, and Dr. Draper Bishop lays stress upon the fact that the emigrants are people of a desirable class and that it is a matter for regret that the prospects of life in newer countries cause them to leave Guernsey. On the other hand, immigration of aliens is also active, and it appears that they are not considered to be equally desirable persons. Dr. Bishop states that the immigrants are answerable for an altogether undue amount of crime and drunkenness, and that [illegible] rather than of British origin. The death-rate for 1912 was a low one 13·1 per 1000, as compared with 14·9, the average for the previous ten years. This circumstance in Guernsey, as on the mainland, is largely to be attributed to the cool and wet summer which favoured a low rate of infantile mortality. There was not a single death in 1912 from epidemic enteritis, which had caused 60 deaths in the previous year, and there were only two deaths from measles and none from whooping-cough, as compared with 18 and 11 respectively in the previous year. On the other hand, diphtheria seems to be considerably prevalent, 139 cases of this disease being included among the total of 270 cases of notifiable infectious diseases admitted to the King Edward Sanatorium during the year. As this sanatorium is only designed for the accommodation of 22 patients, its capacity has often been taxed to the limit, and at times it has been greatly overcrowded. In the parts of the island remote from the town Dr. Bishop considers that the belief in "witchcraft" and "overlooking" which still obtains has much to do with the spread of diphtheria. He also points out that the prevalence of infectious diseases generally is often maintained through the reluctance of the class termed "stranger poor" to make application to the proper authorities for medical relief. The system by which the poorer classes of the island can receive medical treatment, indeed, appears to be very deficient on account of the requirement that the patient, no matter where he lives, can only be attended by [illegible] steps appear to have been taken to deal with this disease beyond the routine disinfection of rooms which have been occupied by consumptive persons. Dr. Bishop rightly points to many of the natural advantages of the island from the public health point of view, such as its abundant sunshine and its tubercle-free milk, but he also indicates that there are serious deficiencies in its sanitary organisation which cannot fail to be detrimental both to residents and visitors. While he considers that it would be unadvisable to cumber the local statutes by the inclusion of the many Acts and Regulations at present in force in England, he points out that the powers of the Board of Health need to be expanded so as to form one working sanitary authority for the whole island. Such an authority should devote its first attention to the improvement of the water supply, the extension of the system of drainage in cc[illegible] and disposal of [illegible] sanitary dwellings for the working classes, and the medical inspection of the school children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8475 births and 4936 deaths were registered during the week ended Saturday, Sept. 27th. The annual rate of mortality in these towns, which had been 13·8, 14·5, and 14·3 per 1000 in the three preceding weeks, slightly rose to 14·4 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the annual death-rate in these towns averaged 12·7, against 11·8 per 1000 in London during the same period. Among the several towns the death-rate last week ranged from 5·4 in Ilford, 6·5 in Hornsey, 6·7 in Gillingham, 7·3 in Willesden, and 7·9 in Carlisle, to 21·8 in Rochdale, 22·0 in Bury, 22·6 in South Shields, 23·6 in Stockport, and 24·0 in Sunderland.

The 4936 deaths from all causes were 38 in excess of the number in the previous week, and included 1081 which were referred to the principal epidemic diseases, against 1242 and 1118 in the two preceding weeks. Of these 1081 deaths, 927 resulted from infantile diarrhœal diseases, 49 from whooping-cough, 38 from diphtheria, 31 from measles, 19 from scarlet fever, and 17 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 3·2 against 3·6 and 3·3 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 960, 1104, and 983 in the three preceding weeks, further declined to 927 last week; of this number 191 were recorded in London, 65 in Birmingham,

---

[1] THE LANCET, Sept. 20th, 1913, p. 883.

54 in Liverpool, 36 in Manchester, 32 in Hull, 24 in Leeds, in Sheffield, and in Sunderland, 22 in West Ham, and 21 in Bradford. The deaths referred to whooping-cough, which had been 31, 38, and 44 in the three preceding weeks, further rose to 49 last week, and included 11 in London, 5 in Sheffield, 4 in Manchester, and 3 in Norwich. The fatal cases of measles, which had steadily declined from 77 to 20 in the nine preceding weeks, rose to 31 last week; 4 deaths occurred in London, in Oldham, and in Sheffield, 3 in Stoke-on-Trent, 3 in Dudley, 2 in Manchester, and 2 in Sunderland. The deaths attributed to diphtheria, which had been 45, 36, and 40 in the three preceding weeks, declined to 38 last week, and included 7 in London, 3 in Leeds, and 2 each in Bristol, in Birmingham, and in Birkenhead. The deaths referred to scarlet fever, which had been 17, 28, and 18 in the three preceding weeks, were 19 last week, of which number 5 were registered in Birmingham, 3 in Manchester, 3 in Sheffield, and 2 in London. The fatal cases of enteric fever, which had been 13, 10, and 13 in the three preceding weeks, rose to 17 last week, and included 4 in London, 2 in Manchester, and 2 in Hull.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had been 2112, 2211, and 2355 at the end of the three preceding weeks, had further risen to 2570 on Saturday last; 508 new cases were admitted during the week, against 298, 346, and 473 in the three preceding weeks. These hospitals also contained on Saturday last 913 cases of diphtheria, 198 of whooping-cough, 79 of measles, and 57 of enteric fever, but not one of small-pox. The 1167 deaths from all causes in London were 20 fewer than the number in the previous week, and were equal to an annual death-rate of 13·5 per 1000. The deaths referred to diseases of the respiratory system, which had been 132, 132, and 125 in the three preceding weeks, rose to 134 last week, but were 35 below the number in the corresponding week of last year.

Of the 4936 deaths from all causes in the 96 towns, 157 resulted from various forms of violence and 331 were the subject of coroners' inquests. The causes of 30, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 72 other smaller towns. Of the 30 uncertified causes of death, 5 were registered in Birmingham, 4 in Liverpool, 3 in Stoke-on-Trent, 3 in Sunderland, and 2 each in Bury, in Burnley, and in Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1075 births and 653 deaths were registered during the week ended Saturday, Sept. 27th. The annual rate of mortality in these towns, which had been 16·7, 16·4, and 14·4 per 1000 in the three preceding weeks, rose to 15·1 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the mean annual death-rate in these towns averaged 14·3, against a corresponding rate of 12·7 per 1000 in the 96 large English towns. Among the several towns the death-rate last week ranged from 7·2 in Coatbridge, 8·5 in Clydebank, and 9·7 in Paisley, to 19·5 in Dundee, 19·9 in Ayr, and 20·3 in Hamilton.

The 653 deaths from all causes were 28 in excess of the number in the previous week, and included 90 which were referred to the principal epidemic diseases, against 126 and 94 in the two preceding weeks. Of these 90 deaths, 55 resulted from infantile diarrhœal diseases, 10 from measles, 10 from diphtheria, 6 from whooping-cough, 5 from scarlet fever, and 4 from enteric fever, but not one from small-pox. These 90 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·1, against 3·2 per 1000 in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 89, 96, and 62 in the three preceding weeks, further declined to 55 last week, and included 25 in Glasgow, 9 in Dundee, 5 in Paisley, and 3 in Aberdeen. The deaths referred to measles, which had been 14, 12, and 9 in the three preceding weeks, were 10 last week, and comprised 7 in Glasgow, 2 in Hamilton, and 1 in Leith. The fatal cases of diphtheria, which had been 6, 7, and 8 in the three preceding weeks, further rose to 10 last week, of which 4 occurred in Glasgow and 2 in Aberdeen. The deaths attributed to whooping-cough, which had been 6, 5, and 9 in the three preceding weeks, fell to 6 last week, and included 4 in Glasgow. The 5 deaths referred to scarlet fever, of which 3 were recorded in Glasgow, were equal to the average in the five preceding weeks. The 4 fatal cases of enteric fever, comprising 2 in Perth, 1 in Glasgow, and 1 in Falkirk, were slightly above the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 86, 65, and 63 in the three preceding weeks, slightly rose to 66 in the week under notice; 26 deaths resulted from various forms of violence, against 25 and 17 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 665 births and 483 deaths were registered during the week ended Saturday, Sept. 27th. The annual rate of mortality in these towns, which had been 19·9, 21·1, and 19·8 per 1000 in the three preceding weeks, rose to 21·0 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Irish towns averaged 18·2 per 1000; in the 96 large English towns the corresponding rate did not exceed 12·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 21·2 in Dublin (against 13·5 in London and 16·2 in Glasgow), 19·5 in Belfast, 24·5 in Cork, 22·9 in Londonderry, 17·6 in Limerick, and 26·6 in Waterford, while in the 21 remaining smaller towns the mean death-rate was equal to 21·6 per 1000.

The 483 deaths from all causes were 28 in excess of the number in the previous week, and included 103 which were referred to the principal epidemic diseases, against 132 and 120 in the two preceding weeks. Of these 103 deaths, 84 resulted from infantile diarrhœal diseases, 9 from whooping-cough, 5 from measles, 3 from scarlet fever, 1 from enteric fever, and 1 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 4·5 per 1000; in the 96 large English towns the corresponding rate was 3·2, while in the 16 Scotch towns it did not exceed 2·1 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 92, 111, and 98 in the three preceding weeks, further declined to 84 last week, and included 33 in Dublin, 22 in Belfast, 8 in Cork, 5 in Londonderry, 3 in Waterford, and 3 in Dundalk. The deaths referred to whooping-cough, which had been 6, 6, and 2 in the three preceding weeks, rose to 9 last week, all of which occurred in Galway. The fatal cases of measles, which had been 10, 2, and 7 in the three preceding weeks, were 5 last week, and comprised 4 in Galway and 1 in Waterford. The 3 deaths attributed to scarlet fever and the fatal cases of enteric fever and diphtheria were all recorded in Belfast.

The deaths referred to diseases of the respiratory system, which had been 42, 41, and 56 in the three preceding weeks, rose to 60 in the week under notice. Of the 483 deaths from all causes, 128, or 27 per cent., occurred in public institutions, and 9 resulted from various forms of violence. The causes of 6, or 1·2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: E. D. J. O'Malley to the *Temeraire* on recommissioning; W. K. Hopkins to the *Vivid*, additional, for the *Fearless*, and on commissioning; J. H. Stenhouse to Bermuda Hospital and Dockyard; W. A. Whitelegge to the *Queen*; F. Fedarb to the *Hibernia*; F. Bradshaw to the *Princess Royal*; E H. Hodnet de Courtmacsherry to Chatham Dockyard; and E. G. E. O'Leary to the *Indefatigable*.

Staff-Surgeons: M. Cameron to the *President*, additional. for Queensferry Sick Quarters, temporarily; and H. J. Chater and J. MacDonald to the *Calypso* and the *Adventure* respectively. Surgeons: O. H. Symons to Malta Hospital and J. G. Boal to the *Temeraire*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Captain Douglas P. Watson is seconded for service under the Colonial Office (*dated Sept. 10th, 1913*).

Lieutenant-Colonel H. M. Adamson has been placed under orders for a tour of service in India, embarking from Southampton on Oct. 22nd, and on arrival will be appointed to the Southern Army. Lieutenant-Colonel T. B. Winter has taken up duty as officiating Assistant-Director of Medical Services to the Colchester District during the absence on special duty of Colonel F. J Jencken. Approval has been given by the Director-General for an exchange on the roster for service abroad between Brevet-Colonel and Lieutenant-Colonel C. H. Melville, in charge of the Military Hospital at Lucknow Cantonment, and Lieutenant-Colonel J. M. F. Shine, in charge of the Military Hospital at Belfast. Lieutenant-Colonel C. C. Reilly has been transferred from the Military Hospital at Colaba, Bombay, to the Presidency Brigade and appointed to hold charge of the Military Hospital at Darjeeling Cantonment. Lieutenant-Colonel H. D. Rowan has been appointed to hold charge of King George V. Military Hospital at Dublin in succession to Lieutenant-Colonel W. C. Beevor, C.M.G. Lieutenant-Colonel H. J. Pocock has been transferred from the Military Hospital at Campbellpore to Murree Cantonment. Lieutenant-Colonel R. J. W. Mawhinny has taken up duty as Senior Medical Officer at Jullunder Cantonment. Lieutenant-Colonel W. T. Mould has been appointed to hold charge of the Military Hospital at Fyzabad Cantonment.

Major P. H. Collingwood has been transferred from medical charge at Honiton Camp to the Military Hospital at Devonport. Major W. S. Crosthwait has taken over charge of the Military Hospital at Upper Topa, Murree Hills District, on transfer from Ambala Cantonment. Major F. Harvey has been placed under orders to embark for a tour of service in India on Oct. 9th, and on arrival will be appointed to the Southern Army. Major B. F. Wingate has taken over charge of the Military Hospital at Bellary Cantonment, Madras Presidency. Major J. H. Brunskill has been transferred from the Military Hospital at the Curragh Camp to the Dublin District, and appointed Specialist Sanitary Officer in succession to Major D. J. Collins, who has embarked for a tour of service in India. Major H. K. Palmer has been appointed to officiate in medical charge of 18th Regiment of Native Infantry, Indian Army, at Aden. Major J. G. Gill has joined for duty at Maymyo. Major E. F. Q. L'Estrange has taken over charge of the Military Hospital at Cannanore Cantonment. Major F. W. Begbie has been appointed Specialist in Operative Surgery to the Fifth (Mhow) Division of the Southern Army in India. Major H. O. B. Browne-Mason has been appointed to officiate as Deputy Assistant Director of Medical Services to the Sixth (Poona) Division. Major A. W. N. Bowen has taken over charge of the Military Hospital at Kirkee Cantonment.

Captain J. W. S. Seccombe has been transferred from the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain, to the Military Hospital at Topsham. Captain J. B. Meldon has taken up duty at Eastbourne on transfer from the Military Hospital at Shorncliffe. Captain G. W. G. Hughes has been appointed to the Military Hospital at Devonport on conclusion of the course of instruction for promotion to the rank of major at the Royal Army Medical College, Grosvenor-road, S.W. Captain P. J. Hanafin has been transferred from King George V. Military Hospital, Dublin, and appointed to hold medical charge at Rogerstown Camp. Captain N. Low has been selected for appointment as Specialist in State Medicine at the recent promotion examination held at the Royal Army Medical College. Captain H. W. Russell has been placed under orders to embark at Southampton on Oct 9th for a tour of service in India, and on arrival will be appointed to the Northern Army for duty. Captain C. P. O'Brien-Butler has been granted one month's extension of general leave of absence home from India. Captain J. C. Sproule has been transferred from the Military Hospital at Devonport to Crown Hill. Captain M. J. Cromie has joined at Chatham. Captain R. H. L. Cordner has been appointed Specialist in Physical Training. Captain J. E. M. Boyd has been allowed to extend his Indian tour of service for one year. Captain M. Keane has joined at Warwick. Captain J. H. Foster has been granted general leave of absence home from India until Feb. 3rd next, with permission to revert to the Home establishment at its expiration. Captain C. J. Coppinger has been selected for appointment as Specialist in Bacteriology. Captain J. G. Bell has been placed under orders to proceed to the Straits Settlements for a tour of service. Captain J. W. Lane has been granted six and a half months' general leave of absence home from the Indian establishment. Captain J. E. Hoar has been appointed Specialist in Dermatology and Venereal Diseases. Captain R. E. U. Newman has been transferred from the Military Hospital at Chatham and appointed to hold medical charge at Landguard Fort. Captain J. W. L. Scott has been appointed to the staff at the Royal Victoria Hospital, Netley, on transfer from Durrington Camp, Salisbury Plain. Captain V. H. Symons has joined for duty at Seaforth. Captain G. E. Ferguson has been selected for appointment as Specialist. Captain P. Power has embarked for a tour of service with the Southern Army in India. Captain C. T. Edmunds has been transferred from the Military Hospital at Bulford Camp, Salisbury Plain, to Sonning-on-Thames. Captain J. A. Renshaw has taken up duty at the Military Hospital, Secunderabad Cantonment, on transfer from the Bangalore Brigade of the Southern Army. Captain R. A. Bryden has been appointed to the Military Hospital at Preston.

Lieutenant C. J. H. Little has been appointed to the Northern Command for duty. Orders have been issued for Lieutenant H. R. L'Estrange, attached to the Military Hospital at Newbridge, to be held in readiness to embark for service in Mauritius on Nov. 1st next. Lieutenant J. B. A. Wigmore has been appointed to the Aldershot Command for duty. Lieutenant E. B. Allnutt has been placed under orders to embark from Southampton for a tour of duty in India on Oct. 9th, and on arrival will be appointed to the Southern Army. Lieutenant N. W. Stevens has been transferred from Shorncliffe to the Military Hospital at Dover. Lieutenant E. P. A. Smith has taken up duty in the Aldershot Command. Lieutenant R. B. Phillips has been transferred from the Military Hospital at Cork and appointed to hold medical charge at Ballcannon Camp. Lieutenant E. A. Strachan has joined at Barry. Lieutenant C. C. Jones has been appointed to the London District. Lieutenant H. Beddingfield has joined the Eastern Command for a tour of duty. Lieutenant W. J. Webster has been placed under orders to embark for a tour of service at Malta. Lieutenant G. H. Dive has joined at Pekin. Lieutenant A. A. M. Davies has been appointed to the Northern Command. Lieutenant T. J. Hallinan has been transferred from the Military Hospital at Lucknow Cantonment to the Presidency Brigade and appointed to the Military Hospital at Fort William, Calcutta. Lieutenant L. Dunbar has been appointed to the Southern Command.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel J. Davison, D.S.O., has arrived home on leave of absence from India. Lieutenant-Colonel W. R. Edwards, C.M.G., has been selected for appointment as Agency Surgeon of [illegible] the Foreign Department of the Govern [illegible] ment from the servi [illegible] Lieutenant-Colonel C. H. James, C.I.E., has been confirmed in the appointment of Civil Surgeon at Simla (West).

Major R. F. Baird, civil surgeon to the Gonda District, has been transferred to Benares. Major J. Husband has been selected for appointment to hold civil medical charge at Dera Ismail Khan. Major H. M. Mackenzie has been granted leave of absence home from India, combined with furlough, for one year and seven months. The services of Major W. H. Kenrick have been placed at the disposal of the Sanitary Commissioner of the Central Provinces for employment on Malaria Survey duty. Major D. McCay, professor of physiology at the Government Medical College, Calcutta, has been appointed Second Physician to the College Hospital, Calcutta, during the absence on special duty of Lieutenant-Colonel B. H. Deare. Major G. Hutcheson, civil surgeon at Aligarh, has been granted leave of absence home from India for one year and eight months. Major F. W. Sumner, on completion of special duty at the Central

Research Institute, Kasauli Cantonment, has been appointed to hold civil medical charge at Farrukhabad.

Captain M. J. Quirke has been appointed permanently to the Civil Medical Department of the Government of Madras Presidency. Captain R. H. Bott has been appointed to officiate as Professor of Surgery at the Government Medical College, Lahore, during the absence on leave of Lieutenant-Colonel E. V. Hugo. Captain P. S. Mills has arrived home on leave of absence from India. The services of Captain C. H. Reinhold have been placed at the disposal of the Government of the United Provinces of Agra and Oudh for officiating civil medical employment. Captain M. R. C. MacWatters, officiating civil surgeon, on completion of special duty, has been appointed to officiate as Chemical Examiner, Government Analyst, and Bacteriologist to the United Provinces of Agra and Oudh and to the Central Provinces Administration, in succession to Captain V. B. Nesfield. Captain H. H. Thorburn, agency surgeon to the Foreign Department of the Government of India, has been granted privilege leave of absence for two and a half months. Captain J. F. Crawley has embarked on medical charge of troops on board the transport s.s. *Barjora* for the Persian Gulf. Captain H. P. Cook has been transferred from the Foreign Department of the Government of India for duty under the Education Department. Captain H. Broome has been granted an extension of his leave of absence home from India. The services of Captain L. Hirsch have been placed permanently at the disposal of the Government of Madras for civil medical employment.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Henry Colwell Rook, late Cadet Staff Sergeant, University of London Contingent, Officers Training Corps, to be Lieutenant (on probation) (dated Sept. 4th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

2nd Highland Field Ambulance, Royal Army Medical Corps: Captain John Innes resigns his commission (dated Sept. 27th, 1913).

Attached to Units other than Medical Units.—Charles Ernest Anderson to be Lieutenant (dated July 2nd, 1913).

DEATHS IN THE SERVICES.

Surgeon-Major David Woods, late A.M.S., at Camberley, in his 84th year. He formerly served as a surgeon in the Royal Artillery.

THE MEDICAL DEPARTMENT OF THE RUSSIAN ARMY.

The medical service of the Russian Army has made a great advance. In 1912 hospital commandants were abolished and the senior medical officer was made responsible for the whole of the management of his hospital. There was a mutiny in the Imperial Medical Academy in March, says the *Journal of the Royal United Service Institution*, but the school has been reorganised, and the students are now under military discipline. Of students there are 850, of whom 523 receive their education free. In the field there are four hospital beds with each battalion, and the battalion provides the first dressing station in action, the collecting station is equipped by the brigade or divisional hospital, which hands the sick and wounded over to the ambulance companies for conveyance to the base. The new ambulance cart is two-wheeled with springs and a hood, holding two stretchers and seats besides. It weighs 560 lb. empty, half-a-ton when loaded, and is drawn by a single led horse. A special class of reservists is designated for service in the Red Cross Society's hospitals.

BULLETIN OF THE NAVAL MEDICAL ASSOCIATION OF JAPAN.

The May issue of this well illustrated publication, for the most part printed in the Japanese character, contains a summary in English of its contents, which includes three cases of lymphatic leukæmia; a rare sequela of gastro-enterostomy; and on solitary tuberculosis of the iris and its treatment. In a paper on the von Pirquet's and Calmette's reaction and some clinical observations on tuberculosis the author, Staff-Surgeon R. Takamiya, referring to a report that a large number of tubercular patients have decayed teeth owing to waste of calcium, says that 101 out of 135 patients with this disease observed by him had decayed teeth.

MEDICAL PRACTICE UNDER THE INSURANCE ACT.

(BY OUR SPECIAL COMMISSIONER.)

(Continued from p. 955.)

XXII. (*continued*).—HULL: UNSOLVED DIFFICULTIES.

AT Hull, as in so many other places, the general impression is that "a better fight will be put up next time, for the profession has learnt a lesson." Thus is defeat acknowledged, the necessity of union and discipline proclaimed, and the belief expressed that other contests are likely to occur at no very distant date. When I inquired what was the nearest danger in sight, the general opinion was that a dispute would surely arise if the insurance fund is made to pay for medical attendance for insured persons who are temporarily absent from their own area. At Hull the Medical Committee has passed a resolution refusing to consent to, and protesting against, any deduction being made from the insurance fund so as to form a central fund for such a purpose. Nor will the Medical Committee hear any mention of what is called case values. These vary far too much, and some might represent large sums. It is maintained that there is no power to enforce reductions of the amount the panel doctor is to receive, because some of the insured persons on his list go off in different directions for their holidays. If they can afford holidays, it was said, they can afford to pay the usual fees to the local practitioners at their holiday resorts. None of these plans, nor any other plan to make deductions from the 7*s*. for this purpose, it is thought, could be enforced by law. In any case, this is one of the questions about which it may be necessary to "put up a good fight." Then there are a number of small questions that must be decided in one way or another and over which disputes may well arise. Thus, if a midwife sends an emergency call to a medical man in a maternity case, however complicated the accouchement may prove, he cannot charge more than 15*s*. Last March protests were made, but the Insurance Committee insisted that not more than 15*s*. could be allowed, even if it happened that two or three medical men had been called to one patient. Then even this small fee has to be claimed within 24 hours. In many cases the lowest amount that could be considered adequate remuneration was 2 guineas, for when such emergency cases occur it means that the medical attendant may have to make many calls after the child is born, and the 15*s*. never suffices for these subsequent visits. Therefore, the question arises whether the receiving of 15*s* from the maternity benefit debars the medical attendant from claiming the rest of his account from the mother. Many medical men know nothing about the regulations, therefore they fail to send in their account within the 24 hours, and thus lose the 15*s*. No regulations had ever been sent to them. The Commissioners have been applied to in regard to these matters and some measures must be taken, for it is quite certain that exceptionally difficult maternity cases cannot be undertaken for a fee of only 15*s*.

Socialist Practitioners and the Act.

In regard to the Act itself, the profession at Hull were absolutely united on the economic basis of resistance to the proposed 4*s*. 6*d*. But when this offer was raised to 8*s*. 6*d* the opposition weakened. Such as it was, it concentrated in the hands of the British Medical Association, and some practitioners who had left the Association because further struggle seemed useless rejoined it in the idea that it was about to become a fighting trades union. When, however, the larger sum was offered, several practitioners began to favour the Act, and the fact that they were strong Liberals, in some cases, suggested that party politics were now playing a part. But, on the whole, politics did not interfere with their loyalty to the majority of the British Medical Association division, which includes the East Riding of Yorkshire. Two well-known general practitioners at Hull are active Socialists, and it was interesting to note their attitude. They were opposed to the Act, considering that it must tend to weaken trades unions. They object to it because the Act interferes with the power of the trades unions to borrow, on behalf of their strike funds, money subscribed for their benefit funds. Then they regard the Act as reducing the status of the medical practitioner; it interferes with his freedom, makes a sort of servant of him, and yet does not give him the status of being a State servant. The panel doctor is tied down to stated hours, a semi-State service having been instituted with all the disadvantages and none of the advantages of a genuine State service. Even in the time of year when, as an independent practitioner, it was possible to make arrangements and absent himself occasionally, the panel doctor is to-day obliged to remain at his post, though there is little or nothing for him to do. In its dealing with the people they consider that the Act tends rather in the direction of giving doles to the poor instead of raising the worker by teaching and encouraging him to organise. The insured workers are separated by the Act from the rest of the community. They are labelled and docketed. To the Socialist practitioners the Act appears as a disintegrating measure which, in practice, will tend to weaken the force of those labour organisations, especially the trades unions, that are best able to defend the cause of the workers.

How the Profession Accepted the Act at Hull.

Up to December, 1912, the profession at Hull were quite united in opposing the Act, but at the end of the year when at a meeting a vote was put there were 38 practitioners who voted for and 83 against the Act. Thus it was evident that quite a large minority had been won over and favoured the measure. There were signs of weakening in all parts of the country, particularly as the importation of whole-time men appeared to be more practicable than had been believed possible. Many practitioners who felt they would certainly lose nearly all their practice began to waver, and the remnants of resistance entirely disappeared when, at Christmas, the misunderstanding arose concerning the proposition to negotiate directly with the Friendly Societies. Everyone felt most keenly in regard to the emancipation of the profession from the control of the Friendly Societies and medical aid clubs. No one understood that it had not been proposed to negotiate with the Friendly Societies, but only to entrust them with the collection of subscriptions, while everyone in Hull remembered well what had been meant by subservience to the Friendly Societies.

An amusing episode now occurred. It having been ascertained by the vote recorded above that there were 38 practitioners in favour of the Act, an attempt was made to gather them together, but no one knew all their addresses. Therefore, an advertisement was inserted in the papers; but the printer removed a comma, so that it appeared as if all the members of the profession were invited to the meeting instead of only those who were in favour of the Act. The resulting discussion, as may be imagined, was at first somewhat heated, but eventually those present had a quiet talk, which ended harmoniously by those against the Act passing a vote of thanks to those in favour of the Act for having convoked the meeting. The supporters of the Act pointed out that before the local division of the British Medical Association had decided to oppose it they had passed by a large majority a resolution that "this division would not refuse to work the Act." Thus, instead of refusing, they then left the matter open. By the time other meetings were held the feeling of antagonism to the Act had developed and continued till the end of 1912, but then the decision to fight the Act was reversed. A big majority are now thoroughly in favour of the Act and hope that the terms will be made better step by step as opportunity arises. For instance, the question of mileage round and about Hull has to be settled, for some practitioners have suffered considerable loss through long-distance visits. Still, when in April, 1913, after three months' trial, the question was raised whether the Hull medical men would continue working the Act, not a hand was held up against it.

Need of Meetings and Discussion.

Though the main issue is thus settled, there should, nevertheless, be frequent meetings of the profession. Some months of experience have been acquired concerning the working of the Act, and its difficulties and remaining defects could now be discussed with advantage. Amendments and improvements are still needed, and something must be done to give articulate expression to what is desirable and desired. This is all the more easy, as, after making several inquiries, I think it may be said that there does not remain in the ranks of the local profession any resentment or bitterness of feeling. Correspondence in the lay papers shows that such feeling is not dead everywhere—and I am not wholly surprised that this should be the case—but Hull is spared the troubles of abiding rancour. Though some practitioners have suffered a little by losing patients, the great majority are at present enjoying an increase of income, and this tends towards friendliness. But one grievance which I have noticed in so many towns occurs at Hull as elsewhere. There are many sons and grandsons of wealthy persons who, because they are employed, are insured and claim medical attendance at the contract rate where formerly they paid, and could well afford to pay, full fees.

The Poorest Panel Practice.

A great deal remains to be done to endeavour to equalise the conditions of panel work. Thus, at Hull, I was informed that a practitioner has on his list about 800 picked lives belonging to a very decent class. As a result, there is so little illness among them that, dividing the 800 annual 7*s.* by the number of consultations given, he received 3*s.* 6*d.* per consultation. On the other hand, another practitioner has 1600 to 1700 insured persons on his list. They are not, however, specially selected, but, on the contrary, belong to the worst class, and he calculates that he only obtains 1*s.* 6*d.* per consultation or item. If the system of payment was according to the work done, the poorer the class of insured persons the larger might be the income. Thus the contract system may provide proportionally the largest incomes to those who *do the least work*. This anomaly prevails all over the country. Then—and this concerns more especially very poor practice—there is the altered attitude observed at the hospitals or infirmaries. In many such establishments help is refused to those who can be treated by a panel doctor. Very few medical cases are taken at Hull unless they are admitted as indoor patients; small wounds may be dressed for the first time at the hospital, but after this first care the injured person is told to go to his panel doctor. The result is that, in the poor practice mentioned above, there are a large number of insured persons, notably dock labourers, who need treatment for minor injuries, such as cut hands, sprained ankles, &c., stitches have to be removed, and new dressings put on. There is no difficulty in such work, but it takes a great deal of time. There are not many panel doctors who can afford the services of a nurse; and then, instead of merely writing out a prescription, it is necessary to get hot water, a basin, bandages, antiseptics, &c.; thus a good 15 minutes may well be spent over the dressing of some small injury, especially if this is done in an inadequately equipped surgery with no nurse to help. Previously to the Act, in the days of club practice, all such patients went to the nearest hospital. But there are also some more serious cases that come to the panel doctor. Thus the practitioner, with the large panel practice I have mentioned, had on his list of injured persons two cases of broken legs and a fractured collar-bone. For the latter he had given, out of his own pocket, 10*s.* 6*d.* to get a suitable strap and buckle arrangement. Of course, he was not obliged to spend this money, but it would have been difficult otherwise to treat this particular patient. Then there were two men who had fractured ankles. Few such cases came as club patients before the passage of the Insurance Act. It is just this difference, not between one practice and another, but between the different panel practices, that will need better adjustment. In all the great and poor panel practices there are many slum dwellers, dock labourers, factory girls, casual labourers —underpaid, half-starved, badly housed men and women. The majority of these people do not think either of what is being done for them or of what used to be done. They grumble because they have to pay their share of the insurance money, yet the Act is proving to be of great medical advantage to them. Among this very poor section of the community there are not many who used to belong to Friendly Societies or medical aid clubs. Therefore, for the first time in their lives, they are paying for medical attendance. When to what they themselves give are added the employers' and the State's contributions, it will be seen that some medical men are receiving payment to-day from sections of the community which formerly were attended for nothing or went to charitable institutions. As often as not, these people had no medical attendance at all, whereas now they are receiving competent advice and treatment.

This, in time, must bring about a considerable improvement in the condition of the lowest and the poorest.

Wages and the Act.

At Hull, as elsewhere, there is of course the problem of malingering, and the desire for the establishment of a medical referee was expressed in several quarters. The panel doctor has not the time to play the part of a detective, especially if he has a large list and his waiting-room is crowded with impatient sufferers. The man with the pain in the back who says he cannot stoop or carry would have to be stripped and examined and put through a great variety of tests before it could be ascertained whether he was malingering or not. It stands to reason that sometimes, if the practitioner is over-worked, his story being probable, is believed without much testing. The greatest difficulty is with women and girls, because their wages are so low. For instance, I came across a charwoman who never earns more than 1*s.* 6*d.* a day and a little food, but as she is not employed every day her income hardly exceeds the 7*s.* 6*d.* a week she would receive as sick allowance under the Act. It often happens with badly paid women and girls that life is more enjoyable on their sick allowance with nothing to do than when working hard to earn about the same sum. Then, as these unfortunate women are very susceptible to illness as a natural consequence of the hard lives they lead, it requires very little malingering, a mere exaggeration of symptoms, to get on the sick-list. Thus better wages become an essential condition to the successful working of the Act. Also, it must be borne in mind that the general standard of health will decrease as less robust persons come into the scope of the Act, so that there will be more to do, and yet there is to be no increase in the payment. The profession is insisting on adequate terms for dependents, so that there should be a good precedent to work upon should an attempt be made to bring them into an enlarged insurance scheme. To-day the profession is undoubtedly receiving more money than was the case before the Act, but will this continue if other sections of the community are also forced to insure?

(To be continued.)

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Housing Acts in Scotland.

SOME valuable hints on the provision of houses by local authorities have been published by the Local Government Board of Scotland. They have not been formally issued to the local authorities, but can be obtained from the Board on application. It is pointed out that either common lodging-houses or separate dwellings (including cottages and gardens) may be provided within or without the district of the local authority, and that there is no statutory restriction upon the class of house that may be erected, provided that it is for habitation by the working classes. But a local authority should first satisfy themselves that there is an unsatisfied demand for working-class houses, and that such are not likely to be provided by private enterprise, and should also consider whether they can do anything to stimulate private enterprise by drawing attention to the scarcity of houses, by feuing municipal land at a cheap rate, or by developing this land by forming roads and laying sewers and gas and water mains in advance. No selected site should be purchased until the Board's consent has been obtained to borrowing, and urban or built up sites should be avoided on the score of expense. Discretion is given to a local authority to acquire land either by agreement or by compulsory powers under Section 2 of the 1909 Act. In the preparation of plans a careful regard should be had to local conditions and to the requirements and means of the prospective tenants, while studied attention should be given to the "Memorandum of the Local Government Board on the Provision and Arrangement of Houses for the Working Classes." It is recommended that sketch plans should be submitted informally to the Board's architectural inspector before they are finally adopted by the local authority. The consent of the Board is required to loans for building purposes, and the maximum periods of repayment advised by the Board are (1) 60 years for houses (with shorter terms for roads, drains, fences, &c.) and (2) 80 years for land. Either the annuity or instalment system of repayment may be adopted. If feasible, housing schemes should be on a self-supporting basis, though the Board do not make this a condition of their consent to borrowing.

Glasgow Parish Council and the Treatment of Phthisis.

For some years there has been a considerable diversity of opinion in Glasgow as to the relative responsibility of the parish council and the corporation in the matter of dealing with patients suffering from tuberculosis of the lungs. At a conference held in 1906 the corporation and the parish council were agreed that phthisis should be included as a notifiable disease under the Public Health Act, but little was done until the year 1908. At that time the Local Government Board drew attention to the respective obligations of local authorities and parish councils, and indicated that the local authority should bear the whole expense, even if, until other arrangements were made, the parish council hospitals were utilised. In 1909 the corporation adopted the principle of compulsory notification, but since then they have done little to carry out their responsibilities. The parish council some time ago proposed to take a test case to the Court of Session, but this was deprecated by the Local Government Board, and further efforts were made to get the corporation to assume the burden of costs. At the present time there are over 400 patients suffering from phthisis in the institutions of the parish council, costing about £30 per year each, equivalent to an annual expenditure of £12,000. All this has to be borne by Glasgow ratepayers, whereas if the corporation or public health authority paid this annual cost the sum of £6000 would be saved to the city, because under the new tuberculosis maintenance grant one-half of the expenditure by the local authority on tuberculosis would be repaid out of Government funds. On the other hand, as things exist at present, no contribution is made to parochial authorities. The parish council naturally feel that money is being lost in this way to the city ratepayers, and they are making another effort to force the local authority to take up the question. The corporation also have apparently decided that the time has come for them to move in the matter, and it is a step in the right direction that was taken when last week the health committee of the corporation recommended the purchase by the corporation of Bellefield Sanatorium. This sanatorium was opened in 1904, and conducted by the Glasgow and District Branch of the National Association for the Prevention of Consumption. The sanatorium, situated in Lanarkshire, provides accommodation for 52 patients. The suggested purchase price is £7500 to £10,000 for the sanatorium with all fittings as it stands, and to this suggested agreement certain conditions are to be attached by the corporation as to the money being used directly or indirectly by the association in behalf of persons residing in the city of Glasgow suffering from tuberculosis. At the present time also an extension is being made by the corporation to Ruchill Fever Hospital for the treatment of phthisical patients, and it has been arranged that the small-pox hospital at Robroyston, when occasion permits, shall be used for the same purpose.

Memorial Portrait to a Dundee Practitioner.

On Sept. 24th a memorial portrait to the late Dr. George Lawrence, who died last year, was unveiled at the Dundee Art Gallery. The portrait has been painted by Mr. W. B. Lamond, and bears the following inscription:—

> George Lawrence, M.B., C.M. Born 1871; died 1912. Presented to Dundee Permanent Collection by grateful patients and friends to mark their appreciation of valuable services to the community. September, 1913.

Sept. 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Belfast during 1912.

THE report of the medical officer of health of Belfast for the year 1912 is fuller, more complete, and more satisfactory than any of its predecessors. The statistics in the report are based on a population of 391,974, as estimated by the Registrar-General in the middle of the year. In 1912 the birth-rate was 27·8 per 1000, being 0·6 less than in 1911, and it was, as might be expected, highest among the inhabitants of working-class districts, and lowest among those resident in the better class areas. The death-rate per

1000 was 18 1, which is 0 9 higher than in 1911, but 1 5 lower than the average rate for 1902-11 Of the total deaths (7111) there were 1408 in children under 1 year of age from all causes Respiratory diseases, including pneumonia and pulmonary tuberculosis, caused 2592 deaths—i e, 802 from pulmonary tuberculosis, 799 from pneumonia, and 991 from other diseases of the respiratory system 338 [illegible] berculosis other than pulmonary, [illegible] m whooping cough, 171 from [illegible] diseases, 48 from scarlet fever, 37 from diphtheria, and 17 from typhoid fever If, as Dr Arthur Newsholme teaches, "infant mortality is the most sensitive index we possess of social welfare and of sanitary administration, especially under urban conditions," then the rate in Belfast—129 per 1000 births in 1912—demands some consideration Mr H W Bailie, the medical superintendent officer of health, *seems to hit the great cause* when, on p 54 of his report, he says "There can be no doubt that the removal of all insanitary conditions improves public health generally, but more particularly that among infants, by the prevention of accumulation of refuse, the breeding places for flies" In Belfast house refuse is removed only once a fortnight Mr Bailie suggests in his report "that more frequent removals of house refuse be undertaken, particularly during the summer and autumn months" and he draws special attention to "the existence of hundreds of back passages which require to be paved, drained, and completed as in their present condition they are a menace to public health" If the plan in use in so many Scotch and English cities were adopted in Belfast—that is, the compulsory use of house bins and their frequent emptying—the infantile mortality would in all likelihood decrease It takes those carriers of disease—the flies—a week to come to maturity in their growth, and this pest would be combated by the prompt removal of house refuse As in many other cities the death rate from pneumonia in Belfast keeps very high, in 1912 there were 799 deaths from this disease being 331 in excess of the number in 1911 Is it not time that a campaign was started against this modern urban cause of mortality? One of the special facts brought out in the report is the continued prevalence of scarlet fever, which commenced in an epidemic form in Belfast in the middle of October, 1909 In 1910 there were notified 734 cases of scarlet fever, in 1911 the number was 766, while in 1912 it has risen to 916 (an attack rate of 2 3 per 1000) That is, in three years (1910-11-12) in Belfast 2416 cases have been notified In 1912 the disease was prevalent during the entire year but most so in the last four months There were 48 deaths, which gives a mortality rate of 5 2 per cent of those attacked—a fact indicating that in a number of cases the type of the fever was virulent It is regrettable to find that the epidemic has remained during 1913[1] In the epidemicity of scarlet fever Belfast is having the same experience as many English cities, and the problem of such a long continued epidemic has not yet been solved This medical report of Mr Bailie is a most welcome one indicating as it has done, that the public health department of the City of Belfast has in recent years been greatly improved, and any friendly criticisms made are simply in the direction of trying to improve the public health of the great industrial and commercial city of Ireland, of which its inhabitants are justly so proud

Medical Advisers to Insurance Committees

The secretary of the Irish Medical Committee has sent a circular to the members of the medical profession in Ireland drawing their particular attention to the following resolution which was passed at the last meeting of the Irish Medical Committee —

> That every consult[illegible]
> If he be a medical a[illegible]
> the local secretary of [illegible]
> his option of refusing [illegible]

There is no doubt whatever that in some quarters the feeling against the institution of these appointments is very strong

King Edward VII Memorial, Belfast

At a meeting of the executive committee of the King Edward VII memorial which is to take the form of a new block at the Royal Victoria Hospital for X ray and vaccine therapy, held in the City Hall Belfast, on Sept 23rd, the contract for the building was given to the same firm which built the new hospital The contract will amount to about £14 000, and there is an additional £4000 in reserve for furnishing

PARIS

(FROM OUR OWN CORRESPONDENT)

A Suggested Cause of Appendicitis

A THEORY has recently been advanced which attributes to drinking water a causative role in certain obscure cases of appendicitis It is a remarkable fact that in a family of 16, six who drank only water had to be operated on while the rest escaped Appendicitis has certainly notably increased, especially in the well to do classes, since water drinking became fashionable—i e, within the past 25 years Is this to be ascribed solely to an increased *precision* of diagnosis? Does water contain a hitherto unrecognised microbe of appendicitis? Since many of the patients drank only mineral water or germ free fluids *it must* be a question not of what water supplies, but rather of what it does not remove or destroy The researches of Professor Sabrazès and others have shown that unsophisticated wine may be regarded as a good antiseptic—as *also may* cider, beer, and soured milk—in the absence of which the intestinal microbes germinate freely Appendicitis might be the occasional result of this free germination Professor Jalaguier, whose statistics are numerous, maintains an open mind, for his operation cases are divided equally between the two classes But it must not be overlooked that there are many kinds of appendicitis even tuberculous and cancerous, and that these arise from a variety of causes In any case the hypothesis in question based as it is on a wide collection of facts, appears not without point and calculated to assist in the rehabilitation of wine to its proper place

Tuberculosis of the Aged

Dr Baudet seeks to show that tuberculosis of the aged is much more frequent than is commonly supposed, a fact of importance from both a family and a social point of view In the Department of the Seine in ten years 12 293 aged persons died from tuberculosis so that 5 53 per cent of old people in Paris who died must have been tuberculous The danger to society from this frequency is greater because the aged subject of tuberculosis usually presents the open form with cavities and because in such subjects the tuberculosis is very often unrecognised Dr Baudet adduces examples of these sluggish pulmonary infections, progressing silently without either the patient or the medical man suspecting it This frequency of unrecognised tuberculosis affords an explanation of cases frequently observed by medical men in which families seem particularly predisposed to phthisis Dwelling with an aged relative in apparent good health children of all ages one after another fall victims of the infection or if they do not die are attacked with Pott's disease a white tumour, or a bacillary orchi epididymitis This aged relative sharing the overcrowded miserable lodging, goes out but little, fearing to catch cold, but spares neither kisses nor caresses to the little ones and often sleeps in the same room with them It is not to be wondered at that she coughs somewhat easily gets out of breath and 'catches cold' from time to time, without the least suspicion arising as to her connexion with the recurring deaths These facts show that the measures of disinfection ordained after a death should not be restricted, as is the case under the present law, to the cases of those who died between 2 and 60 years of age Aged or not, known or unknown, such tuberculous subjects disseminate contagion much more than those actually sick, and those about them do not take precautions against a condition which does not appear serious or the nature of which is unrecognised Finally, it must be remembered that even though the child is not born tuberculous he is born particularly "tuberculisable" and it is contrary to the interests of society not to remove the newly born from such a serious menace to disease and death

The Treatment of Burns by Heliotherapy

Dr Aimes has had remarkable success in the treatment of burns, recent or otherwise, by the action of the sun The sun acts on burns bactericidally, destroying the germs by causing active vaso-dilatation which creates a focus of vitality highly favourable to tissue repair and obnoxious to micro-organisms, by its analgetic action, by the formation of a protective pellicle, and by promoting cicatrisation. The technique is easy. Heliotherapy may be purely local or regional, it may be direct without the interposition of glass, of gauze, or of fatty bodies. Insolation should be administered in progressive doses, the head being always protected from the rays.

[1] THE LANCET, Sept 27th, 1913 p 959

The Treatment of Hydrocele by Formol.

M. Morestin has again directed the attention of the Société de Chirurgie to a mode of treatment already advocated by him, and one which seems likely to replace the use of iodine injection. Take the case, for instance, of a one-sided ordinary hydrocele of medium size, with walls supple and uniformly thinned, and containing a completely translucent fluid. The subject lies on his back and the scrotum is lightly painted with tincture of iodine where the puncture is to be made. Anæsthesia, either local or general, is unnecessary, and, moreover, there is no occasion to remove the hair. Taking up the tumour in one hand, M. Morestin inserts in its upper part the needle of a Pravaz syringe. When the needle is fully inserted, its mobility in the cavity is made sure of. A little lower down a trocar is quickly inserted, and nearly the whole of the fluid is evacuated. When the cavity is almost entirely emptied the trocar is withdrawn, and through the Pravaz needle M. Morestin injects 2, 3, or even 4 c.c. of a mixture of equal parts of formol, glycerine, and alcohol. The needle is then withdrawn, and the fluid is caused by light massage of the scrotum to penetrate the recesses of the cavity. No dressing is necessary. The patient remains in bed or not as he pleases. The injection is hardly painful, and the consequent reaction causes very little pain, often none at all, although it is considerable; for the scrotum swells and becomes œdematous, without, however, showing any of the inflammatory reddening usually seen after the injection of iodine. After two or three days the swelling reaches its height. The greater part of the time the patient can get up without experiencing anything worse than weariness. The general health does not suffer, and the patient is deprived of neither appetite nor sleep. In three or four days retrogression begins and takes place rapidly, being finished in from three to five weeks. Long before this time the patient can resume his ordinary life.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The International Congress on First Aid and Ambulance Work.

THE month of September, 1913, will be long remembered in Vienna as the month of scientific congresses, the two most important, from a medical point of view, being the Congress of German Naturalists and Medical Men and the International Congress on First Aid and Ambulance Work. With the first-mentioned one, which was also the larger of the two, were combined the annual meetings of the German Dermatological, Pædiatric, Psychiatric, and Laryngo-Otological Societies. The International Congress on First Aid and Ambulance Work was held here from Sept. 9th to 13th. The number of enrolled members was over 1200, and no speaker was allowed more than 15 minutes, in order to enable the business to be completed within the stipulated four days. The Congress was an interesting manifestation of the achievements of the modern spirit of pity for those who may be in danger or distress, and Austrians might justly feel patriotic satisfaction on finding that their country was foremost in many respects as regards this subject. Apart from the social entertainments, which the representatives of the inviting city and country seem to regard as indispensable, the actual work done in the sections was extensive enough. The papers read before the Congress had to be presented under one of the following ten heads: first-aid in accidents, instruction of non-medical persons in first-aid, first-aid in towns and in country places, first-aid in travelling (with subsections devoted to automobiles, railways, and aeronautics), first-aid on the seashore and on the high seas, first-aid in mining industries, first-aid in conflagrations, in mountaineering, and in sport, and finally the prevention of accidents generally.

Practical Demonstrations in First-aid.

An interesting practical demonstration on first-aid on a large scale was presented to the Congress and the population generally by the Vienna Rettungsgesellschaft (Ambulance Corps). A test alarm was given to the effect that an accident had happened at the racecourse, that some 40 or 50 persons required immediate help because a wooden platform had given way under a mass of spectators, and that many victims had also been trampled on by horses and a panic-stricken crowd. A few minutes after the message arrived an ambulance detachment, consisting of 20 cars, with one medical man and one male nurse on each of them, made its appearance at the scene of the supposed disaster. Boy scouts acted the part of the injured. The methods of first-aid, the bandages ready for use for such cases, as well as the method of distributing the patients to the nearest hospitals, were demonstrated. To each supposed injured person a small board was attached giving information to the hospital staff of the nature of the injury and the treatment adopted, thus enabling the case to be promptly dealt with at the surgical station. A very similar demonstration of life-saving in the water was given a little later, when the methods of bringing out of the water a person unable to swim and of resuscitation of the apparently drowned were practised. The British Royal Humane Society served here as a model for the establishment of a society for first-aid in shipwreck, floods, attempted suicide by drowning, &c. As a matter of fact, it happened by a curious coincidence that just at the time of the demonstration a candidate for self-destruction wanted to drown himself at the scene of the proceedings. Needless to say, his attempt was promptly frustrated.

Exotic Diseases.—Life-saving at Sea.

The Transactions of the Congress contain many interesting papers. The danger of diseases epidemic in Asia being imported into Europe by the continuous stream of Mahomedan pilgrims returning from the hotbeds of plague, cholera, and small-pox in Arabia, was discussed by Dr. Kobler, the head of the Board of Health of Bosnia and Herzegovina. Since the completion of the railway between the Mahomedan holy places and Damascus the quarantine formerly provided by the caravan journey of a week's duration has been lost.[1] The journey now lasts only a few days, and European countries with Mahomedan populations must be on the alert and must provide special pilgrim stations on the frontier for all suspicious cases.—The prevention of loss of life in sea voyages was discussed in a paper by Professor Flamm, who said that watertight compartments should be constructed in the long axis as well as in the cross section of a modern ship, the stability of the vessel being of paramount importance. The number and capacity of the life-boats should be in direct relation to the number of persons on board the ship, and not to the tonnage of the vessel. A modern passenger steamer must have apparatus for wireless telegraphy, must be carefully ballasted by proper storing of the cargo and trimming of the fuel, and must have the fuel stored in fireproof compartments. Medical aid must be provided for each 300 or 500 souls, one medical man and a ship's hospital or ward, with at least six beds, being available. Cork belts must be within easy reach in the berths and on deck.

First-aid in Mountaineering and Aeronautics.

The organisation for first-aid in mountaineering is interesting, and for it thanks are due to the German and Austrian Alpine Society. The paper by the representative of this society gave particulars of the network of ambulance stations spread over the mountains of these countries (mostly the Alps). There are over 200 first-aid outfits distributed amongst them for emergency cases, and the services of a large number of voluntary helpers, as well as of paid officials, have been secured. They chiefly form rescue or search parties, and are supplied with ropes, ladders, and hammocks. Each station contains a first-aid chest, with splints, medicines, stretchers, bandages, and several small first-aid outfits for the authorised mountain guides. These latter have to attend Samaritan classes, where medical knowledge necessary for them is obtained. The Alpine danger signal is now adopted as an international signal, and the recognised guides are trained to deal with the ordinary accidents met with in the mountains, such as snow-blindness, frost-bites, and fractures. Thanks to the efforts of the above-mentioned society many lives have been saved within the last decade by the activity of these courageous mountaineers.—Aeronautics have received much attention of late from the medical standpoint on account of the great danger to life or health. Mr. Hinterstoisser, of the Army Aeronauts, stated in his paper that first of all smoking near an airship or aeroplane was distinctly criminal. Nobody should rush to the place where any air craft was preparing to descend. Medical attendance should be obtainable within an easy distance of an aerodrome, and a portable first-aid outfit should be ready at hand, as well as fire-extinguishing apparatus. Persons with an unstable circulatory or respiratory system should not meddle with aeronautics, and perfect hearing was also necessary for a would-be airman.

---

[1] THE LANCET, 1908, vol. i., p 1799; vol. ii., pp. 971, 1104, 1248, 1405.

First-aid in Alcoholic Intoxication.

A good paper was devoted to first-aid in cases of serious alcoholic intoxication. Hitherto the majority of such persons have been dealt with by the police in a decidedly offhand fashion, the attendance of a qualified medical man being deemed unnecessary. Serious mishaps, however, have occurred now and then, with disastrous results to the patient, when bodily illness or injury has been mistaken for alcoholism and treated as such. Every person found helpless in the streets and suspected of alcoholic intoxication should therefore be put in special "awakening wards" and examined by the police surgeon. The coma of alcoholic intoxication was not less dangerous, it was explained, than coma due to any other cause, and responded better to correct treatment.

First-aid after Explosions in Mines and at Fires.

First-aid after explosions in mines was the subject of another interesting paper. The composition of the explosives used for blasting purposes was said to have a direct relation to the vitiation of the air in mines. Harmless by-products are formed in the combustion of several of the newer explosives, which in Austria are a monopoly of the Government, and are not allowed to be extensively employed. Various unfortunate incidents have led to very elaborate life-saving appliances being constructed and kept in readiness for use in this country. An exhibition of smoke-caps, electric searchlights to be carried on the head, and similar first-aid apparatus for mining disasters, including a fireproof suit of clothes, with airtight headpieces, an air reservoir, and chemicals for the removal of carbon dioxide from air which was to be breathed again, was much admired. A similar exhibit of the Vienna fire brigade attracted much attention. The latter comprised fireproof ladders, ventilators, and electric lights for use in buildings filled with dense smoke, whilst the Vienna Rettungsgesellschaft showed its portable kitchen for feeding people left without resources after great conflagrations and similar calamities. This kitchen outfit did excellent service at the scene of the memorable earthquake of Messina, when thousands of destitute survivors were dependent upon it for their daily meals.

I intend to send you a further account of this interesting meeting.

Sept. 29th.

ROYAL ALBERT INSTITUTION, LANCASTER.—The nin [illegible] will be held on Tuesday, Oct [illegible] meeting will be held in the De [illegible] under the presidency of Lord Richard Cavendish, chairman of the central committee. The institution, with the schools and workshops, will be open for inspection from 10.30 to 12 30. The presentation of long-service medals will be made by the Lady Moyra Cavendish at 12 o'clock. The medical superintendent, Mr. Archibald R. Douglas, will receive a gold medal for 17 years' service. The Countess of Derby will open the new Farm Colony Building at 12.30 P.M., and an address will be given by Mr. A. H. Trevor, Commissioner in Lunacy. A public meeting will be held in the De Vitré Hall at 2.15 P.M. under the presidency of the Earl of Derby, G.C.V.O. Addresses will be given on The Feeble-minded: Historical Retrospect, by Sir T. Clifford Allbutt, Regius Professor of Physic, Cambridge University; on the Future of the Royal Albert Institution, by Sir James Crichton-Browne, Lord Chancellor's Visitor in Lunacy; and on the After-care of the Feeble-minded, by Dr. C. Hubert Bond, Commissioner in Lunacy.

Correspondence.

"Audi alteram partem."

THE LATE DR. FRANK BUSZARD.

To the Editor of THE LANCET.

SIR,—For 40 years Dr. Frank Buszard undoubtedly held the premier position amongst the medical men of the South Midlands, and his death has left a blank which it will take a long time to fill. I should like to add a few words to the brief obituary notice which appeared in THE LANCET of Sept. 20th. Dr. Buszard was born at Lutterworth 74 years ago, the son of Marston Buszard, who practised in that town for many years, and whose father before him had also been a medical man, so Dr. Buszard in a way was steeped in medical tradition. He was educated at Rugby School, afterwards joined Guy's Hospital, where he had a distinguished career, and there is little doubt that if he had remained in London he would have taken a very prominent place in medical circles. Fortunately for Northampton, he decided to enter for the post of house surgeon at the Northampton General Infirmary, as it was then called, and after a strenuous contest (for one had to canvass all the governors) he was elected, and for some six years he filled the post. In those days there was no assistant house surgeon; he singlehanded had to look after the surgical and medical wards, and as one or two of the honorary staff were aged he had a very considerable share in the treatment of the patients. He rapidly won the confidence of the public, and when at the termination of his house surgeonship he started in practice in Northampton he soon achieved success, and his position was an assured one. In 1876 Mr. Mash, the senior surgeon, retired, and Dr. Buszard was elected to the vacant post. In those days he was a bold and skilful surgeon, and took a very keen interest in ophthalmic surgery, in which he had had special training at Moorfields. In 1878 Dr. Francis, the senior physician, retired, and Dr. Buszard resigned the office of surgeon and became physician to the hospital, a position which he held till his retirement about a year ago, when he was appointed consulting physician. In these days of specialism I suppose it will be a long time before we shall come across a medical man who had such a wide and varied knowledge of disease. Added to this—and assuredly a tremendous advantage—was a fine presence, a most kindly way in treating patients, and an invincible optimism which often helped to tide patients over the most critical periods. Dr. Buszard was a gentleman in the truest sense of the word, and for some 30 years he had the cream of the consultative work in Northampton and some 20 miles round. When it was suggested by either the patient or his friends that Dr. Buszard should be called in, one always welcomed the wish, as the medical man felt that he was certain to be helped in every way. I do not know if I am right, [illegible] a great deal [illegible] from Sir Wi[illegible] Buszard as one of his most distinguished pupils.

His interests were not confined simply to medicine; he was elected an alderman in 1881, retired from that position after a short time to fight a ward, when he was defeated, but shortly afterwards he was elected to another ward, and he held the position for 18 years. For the greater part of this time he was chairman of the public health committee, and most valuable services he rendered to Northampton in eradicating slums and improving the health of the people. He was very strong in his opinion that medical men should attempt to enter into public life, and always encouraged the younger men in their efforts to do so. He was a fluent speaker and a most capable debater, and I feel sure that I am stating a fact that when he left the Northampton town council it lost its most distinguished member. He was an ardent Conservative, often spoke at political meetings, and, though a strong partisan, his opponents always appreciated his keen and vigorous thrusts at their weak spots. For many years he was churchwarden of Dallington Church, and in the evening read the lessons. When I came to the town 30 years ago he was very devoted to lawn tennis and a very skilful player; this he kept up until osteo-arthritis crippled him and prevented him from joining in a four-handed game. As a young man, when at Guy's and the Infirmary, he was an excellent cricketer, excelling as a bat, and in later years we were glad to see him often up at the county ground watching the performances of the county cricket team. In 1911 it was suggested that it would be an appropriate acknowledgment of his many services to present him with his portrait. The idea was taken up very eagerly by all classes, some 200 subscribed to the fund, and Mr. Harris Brown was chosen to paint the portrait and a replica. One hangs in the board room of the hospital, the other was presented to Mrs. Buszard at a gathering of the subscribers in a highly congratulatory speech by the late Marquis of Northampton.

Dr. Buszard's health failed very much during the past year, and in June he finally retired from medical work. About ten days before his death he was seized with gastric symptoms, renal complications occurred, and he passed away on Sept. 14th. He touched life at many points, and he will be long and sincerely mourned by all those who had the privilege of knowing him.

I am, Sir, yours faithfully,
R. A. MILLIGAN.
Northampton, Sept. 29th, 1913.

THE NECESSITY FOR ACCURATE REGISTRATION.

To the Editor of THE LANCET.

SIR,—May I once more ask you for your valuable assistance in reminding members of the profession that, unless their names appear in the Medical Register, they are not "legally qualified medical practitioners" (Medical Act, 1858, Section 34), and that the duty of notifying changes of address rests with them. No person can—

hold any appointment as a physician, surgeon, or other medical officer either in the military or naval service, or in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union, or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health, unless he be registered (Section 36).

And—

no certificate required by any Act now in force, or that may hereafter be passed, from any physician, surgeon, or licentiate in medicine and surgery, or other medical practitioner, shall be valid unless the person signing the same be registered (Section 37).

The Medical Register is the only official publication, and it should not be confused with any of the various directories which issue circulars annually. No one who is not familiar with the work of this office would believe the amount of trouble which is taken to keep in touch with practitioners, and to find them when touch has been lost, but, unless we are assisted by members of the profession themselves, our efforts are often fruitless.

In consequence of cases which have recently occurred, it becomes increasingly important every year that the Registrar should carry out the duty laid upon him under Section 14 of removing from the Register the names of practitioners with whom he cannot communicate. It is done with reluctance, but only by this means can the public and the profession be protected against impostors. No doubt cases of hardship do sometimes arise in consequence of this removal of names, but every possible source of information is made use of to save practitioners from the results of their own forgetfulness, and, if they are inconvenienced by finding that their names are off the Register, the blame does not rest with this office. The duty of notifying changes of address rests with practitioners; the registrar is obliged to send communications to registered addresses only, but the practice is to make use of every available source of information.

I therefore hope that all practitioners who have any doubt as to the accuracy of their address in the Register will communicate with this office without delay, and, if they will give their full names and qualifications in legible writing, it will be of great assistance to us. All communications will be duly acknowledged. Perhaps I may add that by a recent Regulation practitioners possessing medical and dental qualifications, if already on the Medical Register, may register in the Dentists Register, or *vice versâ*, for a reduced fee of £2 1*s*. instead of £5 1*s*.

I should like to take the opportunity of drawing attention to the following resolution adopted by the Council on Nov. 30th, 1911. It cannot be too strongly urged upon practitioners that in giving certificates they are recognised by law as members of a trusted profession, and that it behoves them to exercise the greatest possible care in the matter.

Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes: And whereas such certificates include, amongst others:—

Certificates:—
(*a*) Under any statute relating to births, deaths, or disposal of the dead;
(*b*) Under the Lunacy Acts;
(*c*) Under the Vaccination Acts;
(*d*) Under the Factory Acts;
(*e*) In relation to children or to excusing school attendance;
(*f*) In connexion with Sick Benefit, Insurance, and Friendly Societies;
(*g*) In connexion with workmen's compensation;
(*h*) In connexion with naval or merchant shipping;
(*i*) For procuring the issue of Foreign Office passports;
(*j*) For excusing attendance in courts of justice, in the public services, in public offices, or at ordinary employments;

And whereas it has been made to appear to the General Council from [illegible] medical practitioners have given and [illegible] roper certificates of the above specified [illegible]

Now, therefore, the General Medical Council hereby give notice that [illegible] er who shall [illegible] per certificate, [illegible] otherwise, is [illegible] conduct in a professional respect and [illegible] Medical Register under Section 29 of the Medical Act, 1858.

I am, Sir, yours faithfully,
NORMAN C. KING, Registrar.
299, Oxford-street, London, W., Sept. 26th, 1913.

LORD KELVIN AND THE ETHER OF SPACE.

To the Editor of THE LANCET.

SIR,—In the restful radiance of these southern waters I have been reading in THE LANCET of Sept. 13th your comments on the ether of space in Sir Oliver Lodge's recent address to the British Association, and you have awakened a vivid recollection of an interesting conversation on the genesis and evolution of matter and kindred interests which I had with Lord Kelvin shortly before his death. I had at that time been speaking on the significance of radium emanation and helium, &c., in relation to solar energy, and time, and time estimates, in an address at the centenary meeting of the Geological Society on behalf of the College of Physicians, and on the occasion of our meeting Kelvin brought me an advance copy of a short but very interesting paper, entitled "Gravitational Matter," which may or may not have been published subsequently.

He explained that the first word "*given* a definite quantity" in the opening sentence, though a mathematical commonplace, was also applicable in the creative sense, and it was in response to my quotation from Milton, "Hard thou knowest it to exclude ethereal substance with corporeal bar," which led to the expression of his views on the interstellar medium. Kelvin considered the ether as an all-pervading agent, possessing certain definite attributes of which radiation and gravitation were evidence, and held that any theory of evolution or condensation of ether into gravitational matter would mathematically conflict with the condition precedent that such a medium should exercise no restraint on the perfect mobility of the matter immersed in it. He shrank from asserting that the ether had no "influence" on matter, and deprecated any objections to generally received views on the subject as "whimsical."

Lord Kelvin at that time seemed to stand sceptical or with suspended judgment at the assertion of elementary instability or transformation, and frankly resented the illogical notion of dissecting an atom, but nevertheless in the vast progress since established in our knowledge of matter and of the ebb and flow in universal attenuation and condensation he would surely have taken a leading part, especially perhaps assisting our understanding in the corpuscular character we are inclining to superimpose upon undulatory light, and perhaps imparting a new significance to the ether of space itself.

I am, Sir, yours faithfully,
MICHAEL GRABHAM.
Position approximately N. Lat. 37°, W. Long. 13°,
Sept. 20th, 1913.

THE CORRELATION OF BIRTH-RATES AND DEATH-RATES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of July 19th last there appears a letter by Dr. Binnie Dunlop under the above heading. I desire to draw the attention of Dr. Dunlop to the birth- and death-rates of British Guiana for the last 30 years, since in this colony his contention appears completely wrong:—

Year.	Birth-rate.	Death-rate.	Year.	Birth-rate.	Death-rate.
1883	31·4	30·2	1898	29·6	33·9
1884	29·8	30·6	1899	28·7	29·1
1885	31·6	29·5	1900	37·8	26·1
1886	35·2	25·5	1901	35·9	23·6
1887	32·3	32·4	1902	33·4	28·1
1888	30·8	29·2	1903	29·1	28·9
1889	38·1	28·1	1904	30·3	28·8
1890	30·9	39·8	1905	33·6	27·4
1891	27·0	37·0	1906	32·9	28·8
1892	28·0	39·0	1907	28·3	36·9

Medical Officer of Health.

LOW-PRICED CLINICAL THERMOMETERS: A WARNING.

To the Editor of THE LANCET.

SIR,—The experiences hereinafter set out may serve as a warning to all who are interested in the purchase of clinical thermometers for use in institutions, where, owing to the large number of breakages, there is a natural desire to reduce the cost of these articles as much as possible.

On August 29th three dozen clinical thermometers, at 10*s.* 6*d.* a dozen, were received from a well-known firm of surgical instrument makers. In order to be tested they were all placed together in an upright position and were totally immersed in warm water. After five minutes, during which time the water was continuously agitated, the temperature indicated by each was recorded. The following are the readings in order of removal from the water: 99·4, 98·2, 99, 101·6, 101, 101·2, 98·8, 99·6, 101·6, 100·6, 99·2, 99, 100, 101·6, 99, 99·6, 98·2, 100, 100·2, 99·8, 98·4, 98·6, 99, 98·6, 99·8, 96·4, 99, 98·2, 100·8, 96·8, 98, 98·6, 101·6, 98·8, 99, 100.

These were, of course, returned to the vendors, who replied that they could not guarantee the accuracy of such low-priced articles, but they stated that they could supply really reliable thermometers at 18*s.* per dozen, which they would guarantee to one-fifth of a degree. Three dozen of these were accordingly ordered, and when delivered they were submitted to a similar test. For a given temperature the readings were as follows: 100·2, 100·8, 102·4, 102·6, 102, 101, 101·2, 105, 100·8, 101·6, 100·6, 102·2, 104·4, 104·2, 103·8, 105, 102·8, 104·8, 102, 98, 98·2, 99·6, 100·8, 103·6, 100·4, 102·2, 103, 103·6, 100·2, 99·2, 105·4, 99·4, 100·4, 102·8, 102, 102.

These in turn were rejected, and a third batch (of 18) were supplied. This time a representative of the firm, armed with two thermometers with Kew certificates, attended to witness the testing. As before, the thermometers were placed in warm water, and in addition the two certificated thermometers were also immersed. The latter indicated that the temperature of the water was 98·4. The other thermometers gave the following readings: 97, 95·8, 96·5, 95·7, 96, 96·2, 95·8, 96·5, 96, 95·6, 97, 96·2, 95·4, 97·2, 96·8, 97, 96·9, 97.

The test was then repeated with water that was rather warmer, the Kew-tested thermometers indicating a temperature of 105·2. The others gave the following readings: 102, 102, 101·5, 101·5, 102·2, 101·3, 103, 103, 103·6, 103, 103, 103·4, 102·6, 103·4, 101·4, 103·2, 101, 101·4.

The firm's representative retired crestfallen taking his thermometers with him. Up to the time of writing no further consignment has been received.

I am, Sir, yours faithfully,
J. BASIL COOK,
Medical Superintendent to the St. Giles Infirmary.
Sept. 24th, 1913. Cleveland street, W.

THE SCOPE FOR POST-GRADUATE TEACHING.

To the Editor of THE LANCET.

SIR,—[illegible] ment to [illegible] which, in the [illegible] the table, were all beyond the competence of the general practitioner to perform. The list occupied about three-quarters of a column, enumerating about 50 or 60 operations, and it undoubtedly constituted a damning indictment of the inefficiency of the general practitioner. Incidentally, it is also a fierce slur upon the schools which turn out uncompleted practitioners in such vast numbers every year to make good the waste caused by death and other causes. The general body of inefficient general practitioners is recruited by the qualified but incompetent graduate. That list was published in all good faith in the belief that a doctor in general practice had neither the skill nor the knowledge with which to undertake these operations—that he never had the competence, even at the moment of his graduation, nor had since then had the energy or the field on which to acquire such proficiency. The object of the committee in publishing this list was to support its claim for special fees under the scheme it was pressing upon the acceptance of the Government, but it stands in all its nakedness as the deliberate judgment of the heads of the Association upon the proficiency of the general practitioner. It cannot be supposed that the committee had the cold-blooded intention of wantonly insulting the general practitioner—as far as my reading goes no protest has ever been published in the journal—indeed, the schedule seems to have been received with general acquiescence as comprising pretty well everything in the surgical line that he is unable to perform with efficiency. It seems also to be commonly accepted as true that the general practitioner is not conversant with the developments that have attended the progress of medicine in late years. The technical methods employed nowadays in diagnosis and treatment, the investigations pursued in the modern laboratory, are all assumed to be beyond the ken of the doctor in general practice. [illegible] almost a habit to believe that he is as a rule [illegible] of surgery, his knowledge o[illegible] gynæcology. It would appear to be a case of judgment by default.

I believe the general practitioner is fully alive to his limitations, and is keenly anxious to remove the slur that attaches to the position he occupies in the profession. He does not lay blame on the school for turning him out incompletely equipped for the work he has to perform, but he looks round for a way by which he can proceed to make himself sufficient. Dr. C. O. Hawthorne, in his admirable address at the International Conference on Post-Graduate Medical Education,[1] indicates several paths by which the general practitioner in pursuit of this object may wend his way. Doctors practising in London and the provincial cities provided with schools seem to have abundant means within their reach for "the cultivation of efficiency," though Dr. Hawthorne regrets to find that these means "exercise but little influence on the local profession." It may be that the system of post-graduate education in existence at these centres does not meet the needs or the opportunities of the local profession. In my opinion the practitioner stands most in want of clinical experience—it is essential that he should see and handle cases, see applied the latest methods in diagnosis and treatment, witness operations, and have a short exposition on each case by the demonstrator. Set lectures are in my humble judgment a mistake as they take up too much time. The busy practitioner must have his instruction potted.

Whatever is being done for the city practitioner it will scarcely be denied that the country practitioner, exposed as he is to influences that all tend [illegible] stagnation and deterioration, has been left [illegible]elf and letter (and have left a third step in the toilet, necessary in severe cases, undescribed).—I am, Sir, yours faithfully,

---

Sept. 27th, 1913. H. B. L.

THE NATIONAL INSURANCE ACT AND UNREGISTERED DENTISTS.

To the Editor of THE LANCET.

SIR,—Your leading article of Sept. 20th on "Legislation with Regard to Anæsthetics," and the debate upon the report of the British Association's committee, bring into prominence the dangers of the practice of dentistry by unregistered persons. Is it not a "disadvantage of a public kind" that such practice should be permitted at all? Could not the Government, through the Insurance Committees if in no other manner, help in some measure to protect the public? As matters stand at present, it appears medical men must afford medical benefit to those insured persons who may require it in consequence of having been treated by an unqualified person, though such misconduct on the part of the member *may* bring about the suspension of the sickness benefit. *May* is used advisedly, as I understand one society with branches over a great part of the country actually pays such unregistered practitioners out of its friendly side funds. The model rules say an insured person "shall obey the instructions of the practitioner attending him"; but he does not present himself for attendance until the mischief is done. The total of this extra work thrown upon the profession must be very considerable, and borders on "covering" irregular practitioners. It would be a great boon if some line of action were indicated by which this most involuntary aid to unqualified practice could be abolished or largely diminished. I am, Sir, yours faithfully,

Sept. 29th, 1913. M.B.

THE NATIONAL INSURANCE ACT.

Uniformity in Medical Certificates.

REPRESENTATIONS from many quarters have reached the National Health Insurance Commission pointing to the desirability of securing some uniformity of the medical certificates issued in connexion with claims for sickness benefit under the National Insurance Act. The fact will cause no surprise to those who have seen in THE LANCET references to the difficulties which have arisen owing to the demands of various Approved Societies with regard to these certificates being of a contradictory nature. The Commissioners, in Memo. $\frac{173}{\text{I.C.}}$, divide the medical certificates required to be furnished under the Act into the *initial* certificate, which the insured person must forward to the society with his "declaring on note," the *continuing* certificate, and the *final* certificate. A general acceptance has been secured from the Approved Societies of an *initial* certificate, and the form in question, Form Med. 34, has been supplied for issue to all medical men on the panels, who may use it in lieu of Form Med. 26. But concerning the *continuing* and *final* certificates, a common form cannot be found which is adaptable to the administrative requirements of Approved Societies of every type. Forms, however, marked A.S. 75 and 76, have been issued to Approved Societies for their assistance in framing continuing and final certificates to be used in the future.

Funds arising through Insured Persons not having Chosen their Medical Men: the Position in London.

A curious and unexpected situation has arisen in London owing to the London Insurance Committee not having distributed among the medical practitioners whose names are on their lists a large number of insured persons who have failed to make any selection of a practitioner or "panel doctor" to attend them when sick. The obvious result has been the accumulation of a considerable sum of money, which by the end of the year will, it is estimated, amount to £140,000, and this it is contended by some ought to be distributed among the medical men working under the Act. The opinion of counsel has accordingly been sought by the London Insurance Committee, and Mr. Danckwerts, K.C., has advised that the medical practitioners on the panel are only entitled to be paid definite sums calculated at so much per head of the insured persons on their lists. He is unable to find in the contract any right to claim more, and added that the Committee is "not entitled to make presents or distribute largesse among the panel doctors ...... and cannot, as matters stand, deal with the fund." The matter was discussed at a meeting of the London Insurance Committee, when it was urged by medical members of the Committee that the money in question was in their hands for the remuneration of medical men on the panels and should therefore be paid to them. This view will no doubt be shared by medical men in other localities than London where the same circumstances exist, and possibly the advice of further counsel may be invoked. The first question to be decided is what committees have authority under the Insurance Act to do (not what they ought to do ethically) under conditions which, as we understand the matter, need not be universal and might have been avoided. Without wishing to make any unnecessary personal reference, we would add that Mr. Danckwerts is a barrister who enjoys a high reputation in his profession as a lawyer, and that he has expressed his opinion in terms which suggest no kind of doubt or reservation. The question must receive the careful attention of the Commissioners, who will be asked to receive a deputation from the London Committee on the subject. At the same meeting the receipt was reported of Circular 29 I C from the Commissioners recommending a numerical distribution of unallotted persons quarter by quarter "among the doctors on the panel upon whom rested collectively the responsibility of treating the whole of the insured persons." The Commissioners added that adequate arrangements should be made with the doctors on the panel whereby insured persons entitled to medical benefit who were not yet on a doctor's list should be able to receive treatment without delay if required. The Medical Benefit Subcommittee recommended the Committee, before taking action on these lines, to ask the Commissioners to receive a deputation. In the course of debate Mr. F. Briant, chairman of the subcommittee, suggested a friendly action brought by the medical profession against the Committee to settle the point at issue. Dr. H. H. Mills said counsel's opinion struck at the root of the agreement made between the medical profession and the Chancellor of the Exchequer at the beginning of the year. The claim of the medical service under the Act was that all the money ear-marked for medical benefit belonged to the medical service and that service alone, with the exception of the money in respect of those who had made their own arrangements and the money due to the druggists. Mr. H. Kingsley Wood declared that it would shock the public conscience if payment for 400,000 persons went to doctors on the panel who had not done a stroke of work for the money. Dr. B. A. Richmond urged that the doctors on the panel took the risk of sickness amongst these 400,000 people and were entitled to the money. Mr. E. B. Turner said a very definite impression was given when the medical service was inaugurated that all the money would go to doctors on the panel; consequently the Committee was now in a very unfortunate position. Members could not vote the money for fear of being surcharged.

The Question of Complaints in connexion with Insurance Practice.

The Medical Service Subcommittee of the London Insurance Committee since January has had before it 38 complaints made by patients against medical practitioners on the panel, of which 20 were substantiated, and two complaints, both proved, lodged against patients by medical practitioners. The subcommittee has recommended that the practice hitherto pursued shall be continued of only disclosing the name of a medical practitioner complained of when the committee has carried the matter before the Insurance Commissioners with a view to the practitioner being removed from the panel, and when the Commissioners have held the allegations thus made to have been proved. This practice follows the obvious analogies provided by the General Medical Council, the Incorporated Law Society, and the Pharmaceutical Society of Great Britain.

The Amenities of Panel Practice.

"Just because you pay a penny or so a week you imagine that a doctor is to be ordered about like a dog at any moment of the day or night. If the doctor in the most generous way had not put in a plea for you I should have made it a heavy penalty." In these terms Mr. D'Eyncourt, sitting at Clerkenwell police court, admonished a man who, in a drunken condition, had roused a medical man on whose list of patients the man's wife was included, and sent him at midnight to look for a supposed dying woman who, as a matter of fact, was able to go to work, and who had removed from the address at which she was entered as residing. The defendant was charged with using abusive language, and bound over in the sum of £5 to behave himself for 12 months.

The Cost of Medicine for Insured Patients.

Attention having been drawn at Manchester to the possibility of the Insurance Committee not being able to cover the cost of drugs supplied to patients under the Act through the fund at its command being insufficient, correspondence has taken place in the *Manchester Guardian* which merits attention. The Manchester Pharmaceutical Association Insurance Committee has intimated that it considers that the drug fund, if carefully administered, will meet the demands made upon it under normal conditions if the money be spent on drugs taken at their market value *plus* the cost of preparation. The deficiency, if any, it is suggested, will be due to special brands of drugs being ordered and through payment for "trade marks and proprietary values" being demanded. This, however, does not mean that the prescription of proprietary articles to panel patients is always regarded by Insurance Committees as extravagant, and, indeed, to take up this position would be quite impossible. A few days ago Messrs. E. T. Pearson and Co., Limited, were informed by the London County Insurance Committee that lactagol and the vasogen compounds could be prescribed for panel patients, and that the charges therefor would be passed by the committee, and other Insurance Committees have adopted the same attitude in similar cases.

The Appointment of Medical Referees in London.

The London Insurance Committee have decided to divide London into six districts for the purposes of the appointment of medical referees, instead of four, as originally proposed. The terms of the appointment were fixed at 7*s.* 6*d.* for each examination and report, and reasonable travelling expenses beyond two miles. The Commissioners have only approved [illegible] a period ending at C[illegible] ments were made: [illegible] wark, M.D., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond. North District.—John Herbert Burroughs, M.R.C.S. Eng., L.R.C.P. Lond. East District.—John Fletcher Porter, M.B. Lond., L.S.A. South-East District.—Hugh Davies, M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond. South District.—Eric Bayley, M.D., B.S. Lond., F.R.C.S. Eng. South-West District.—Reginald Crosse, B.A. Cantab., M.R.C.S. Eng., L.R.C.P. Lond.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination held on Sept. 23rd, 24th, 25th, and 26th the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Edgar Richard Batho, St. Paul's School; [illegible]

Chemistry.—William Bl[illegible] Hospital; John Ryt[illegible] Middlesex Hospital; [illegible] Edward Fasken, Guy'[illegible] and Frederic Francis [illegible]

Physics.—H[illegible] George W[illegible] Middlesex [illegible] versity; a[illegible]

Biology.—E[illegible] St. Thom[illegible] Christoph[illegible] Nelson, I[illegible] Wilson T[illegible] pital; E[illegible] Bertram [illegible]

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Alice Maud Mary Clegg, Eastern District Secondary School, Douglas; Robert Peter Dewar, London Hospital; Morgan James Evans, Transvaal University, Johannesburg, and Birmingham University; James Ernest Horton, London Hospital; Lionel Beresford James, Bristol University; Ernest Arthur West, Wolverhampton Grammar School; Lindsay William Wilson, London Hospital; and Robert Wolff, Royal Dental Hospital.

Chemistry.—Walter Kember, Liverpool University; Reginald John Newman, London Hospital; William James Robinson, Charing Cross and Royal Dental Hospitals; Percy Williams, Holt School of Science, Birkenhead, and Claude Young, Royal Dental Hospital.

Physics.—George Frederick Harry Bloom, Darlington Technical College; Norman Douglas Green, Eastern District Secondary School, Douglas; Geoffrey Miles Haydon and William Grant Milton, Bristol University, and Frank Watson Stiven, Birkbeck College and Guy's Hospital.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in September the following candidates satisfied the examiners:—

FIRST M.B. EXAMINATION.

[illegible] C. Fiddes, [illegible]

DIPLOMA IN DENTISTRY.

[illegible] G. P. Anderson and G. C. Porley. [illegible] Cardwell, Harry [illegible] W. H. D. Quinn, [illegible] inson, and N. H. Wood.

THE CHADWICK LECTURES ON SANITARY SCIENCE.—The syllabus of these lectures, which are delivered free to the public, has just been issued, and during the next four months several series of three lectures will be given at London, Glasgow, Bristol, and Southampton, on Sanitation in Various Aspects. A [illegible] medical men will preside, [illegible] Sir Isambard Owen, Sir [illegible] Herringham. In the first half of October, at Glasgow, Mr. W. E. Riley, superintending architect to the London County Council, will give three lectures on Practical Problems of Housing Reform, and in the last weeks of the month Dr. Leonard Hill at Bristol will take for his subject the Physiological Principles of Heating and Ventilating. During November Sir George Newman, chief medical officer to the Board of Education, and Mr. W. Addington Willis will respectively discuss the Place of the Open-air School in Preventive Medicine and House Drainage Law; while at Southampton Surgeon-General G. J. H. Evatt will take for his subject the History of Physical Efficiency in the Army. In January Dr. Killick Millard will lecture on Vaccination in the Light of Modern Experience. The lectures in London will be held at the University of London, the Institution of Civil Engineers, Westminster, and at Toynbee Hall, Whitechapel. Full particulars can be obtained from the secretary, Mrs. Aubrey Richardson, 8, Dartmouth-street, Westminster.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE (UNIVERSITY OF LONDON).—After an examination held [illegible] Science have [illegible] cholarships of [illegible] urch, Oxford, [illegible] e, Cambridge. 2. *Junior Science Scholarship of £150*: J. P. Ross, of [illegible] Preliminary Sci[illegible] Department, St. Bartholomew's Hospital. 3. Arts: [illegible] Dick, of Epsom College, and L. [illegible] College (equal). 4. Jeaffreson Exhibition of £50: R. J. Perkins, of Bedford Modern School.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. J. P. [illegible] of the oldest members of the [illegible].—Dr. Franz C. Müller, court [illegible] eminent [illegible] aged 53. He [illegible]

Metropolitan Hospital, Kingsland-road, N.E.—House Physician and House Surgeon. Salary at rate of £60 per annum, with board and washing. Also Assistant House Physician and Assistant House Surgeon. Salary at rate of £40 per annum, with board and washing. All for six months. Also Pathologist and Registrar. Salary at rate of £120 per annum. Also Assistant Physician.

Middlesbrough, North Ormesby Hospital.—Assistant House Surgeon. Salary at rate of £100 per annum for first six months, and £110 per annum afterwards, with board, apartments, washing, and attendance.

Middlesex Hospital, W.—Dental Surgeon

Newcastle-upon-Tyne Education Committee.—Second Whole-time Assistant Medical Officer. Salary £250 per annum.

Newcastle-upon-Tyne, Hospital for Sick Children.—Senior Medical Officer and Junior Medical Officer for six months. Salary £100 and £80 per annum respectively, with board, lodging, and laundry.

Newcastle-upon-Tyne, University of Durham College of Medicine.—Lecturer in Diseases of the Throat, Nose, and Ear, Diseases of the Skin, and Diseases of Children.

Northampton County Asylum, Berry Wood, Northamptom.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing.

Nottingham General Hospital.—Assistant House Physician. Salary £100 per annum, with board, residence, and laundry.

Oxford County Asylum, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing.

Paddington Green Children's Hospital, London, W.—House Physician and House Surgeon for six months. Salary at rate of £52 10s. per annum in each case, with board and residence.

Park Hospital for Children, Hither Green, London, S.E.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing.

Perth, James Murray's Royal Asylum for Lunatics.—Physician-Superintendent. Salary £700 per annum, with furnished house, &c.

Plymouth, South Devon and East Cornwall Hospital.—House Physician for six months. Salary £75 per annum, with board, residence, and washing.

Portsmouth Royal Hospital.—House Surgeon for six months. Salary £80 per annum, with board, &c.

Preston, County Asylum, Whittingham.—Assistant Medical Officer, unmarried. Salary £200 per annum, with board, apartments, and washing.

Prince of Wales's General Hospital, Tottenham, N.—Honorary Assistant Ophthalmic Surgeon. Also Senior House Physician and Senior House Surgeon. Salary £75 each per annum. Junior House Physician, Assistant Pathologist, and Junior House Surgeon. Salary £60 each per annum, with residence, board, and laundry. All for six months.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Clinical Assistants in Out-patient Department for Medical, Surgical, and Eye cases. Also Assistant Physician.

Reading, Royal Berkshire Hospital.—House Surgeon and Second House Surgeon for six months. Salary in each case £80 per annum, with apartments, board, and washing.

Rochdale Infirmary.—Second House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

Royal Free Hospital, Gray's Inn-road, W.C.—Male and Female House Physicians and House Surgeons for six months. Board, lodging, and washing provided. Also Female Junior Obstetric Assistant for six months. Board, lodging, and washing provided.

Royal Hospital for *Diseases* of the Chest, City-road, E.C.—Clinical Assistants in the Out-patient Department.

Royal London Ophthalmic Hospital, City-road, E.C.—Senior House Surgeon. Salary £100 per annum, with board and residence.

Royal National Orthopædic Hospital.—Two Resident House Surgeons, unmarried, for six months. Salary at rate of £100 per annum, with board, residence, and washing.

St. Mary's Hospital for Women and Children, Plaistow, E.—Junior Resident Medical Officer for seven months. Salary at rate of £70 per annum, with residence, board, and laundry.

Scalebor Park Asylum, Burley-in-Wharfedale.—Assistant Medical Officer. Salary £180 per annum, with board, apartments, attendance, &c.

Scarborough Hospital and Dispensary.—Senior House Surgeon and Junior House Surgeon. Salary £100 and £80 per annum respectively, with board, residence, &c.

Sheffield Union Hospital, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £120 per annum, with apartments, rations, &c.

Shrewsbury, Salop Infirmary.—House Physician. Salary at rate of £90 per annum, with board and apartments.

Southampton, Royal South Hants and Southampton Hospital.—House Physician. Salary at rate of £100 per annum, with rooms, board, and washing.

Swansea General and Eye Hospital.—House Surgeon. Salary £125 per annum, with board, washing, and attendance.

Taunton, Somerset and Bath Asylum, Cotford.—Assistant Medical Officer, unmarried. Salary £180 per annum, with apartments, board, washing, attendance, &c.

Wakefield General Hospital.—Second House Surgeon, unmarried Salary £100 per annum, with board, lodging, and washing.

Warrington, Lancashire County Asylum, Winwick.—Assistant Medical Officer. Salary £200 per annum, with board, apartments, attendance, and washing.

Warrington Union.—Assistant Resident Medical Officer. Salary £150 per annum, with apartments, rations, &c.

West Bromwich and District Hospital.—Assistant Resident House Surgeon and Anæsthetist, unmarried. Salary £75 per annum, with board, residence, and washing.

West Ham and Eastern General Hospital, Stratford, E.—Junior House Surgeon. Salary at rate of £75 per annum.

Westminster Union Infirmary, Colindale-avenue, Hendon, N.W.—Assistant Medical Officer. Salary £160 per annum, with board, residence, and washing.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary at rate of £120 per annum, with board and lodging.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Junior House Surgeon. Salary £100 per annum, with rations, apartments, and washing.

Wisbech Union.—District Medical Officer and Public Vaccinator. Salary £53 per annum.

York Dispensary and Maternity Hospital.—Resident Medical Officer, unmarried. Salary £140 per annum, with board, lodging, and attendance.

The Chief Inspector of Factories, Home O[illegible] notice of vacancies as Certifying Surgeo[illegible] Workshop Acts at Clacton-on-Sea, in t[illegible] Gillingham, in the county of Dorset; at [illegible] Bedford; at Willenhall, in the county of [illegible] in the county of Suffolk.

Births, Marriages, and Deaths.

BIRTHS.

Derry.—On Sept. 25th, at "Windspoint," Higher Drive, Purley, Surrey, to Dr. and Mrs. D. E. Derry, a daughter.

Griffin.—On Sept. 22nd, at Baldock, Herts, the wife of John P. Griffin, M.R.C.S., L.R.C.P. Lond., of a daughter.

MARRIAGES.

Mole—Holmes.—On Sept. 30th, at St. Gabriel's, Warwick-square, S.W., by the Rev. L. H. Nixon, M.A., Precentor of Westminster, and the Rev. Noel Kynaston Gaskell, Curate of St. Gabriel's, Harold F. Mole, F.R.C.S., of 19, Mortimer-road, Clifton, son of the late F. M. Mole, of Westfield-road, Edgbaston, to Harriet (Hettie), youngest daughter of the late Reuben Holmes, of Heanor, Derbyshire.

Pearce—Stirling.—On Sept. 27th, at the Church of the Holy Innocents, Fallowfield, Manchester, by the Rev. Eric G. Southam, Percival Leslie Pearce, M.B., Ch.B., second son of the late Mr. and Mrs. William Pearce, of Kingston, Jamaica, to Elizabeth Ferguson, elder daughter of William Stirling, M.D., D.Sc., Belfield Lodge, Fallowfield, Manchester. At Home Nov. 25th and 26th, Enfield House, Bury Old-road, Manchester.

Sandison—Gold.—On Sept. 4th, at the South Croydon Congregational Church, Alexander Sandison, M.B., B.C., B.A. Cantab., B.Sc. Lond., of Croydon, to Esther Catharine, eldest daughter of Mr. and Mrs. Gold, of Croydon.

DEATHS.

Brown.—On Sept. 30th, at Fitzjohn's-avenue, N.W., William Carnegie Brown, M.D., M.R.C.P., aged 54 years.

Norris.—On Sept. 29th, at City Walls, Chester, Deputy Surgeon-General Nathaniel Norris (Retired List), in his 83rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

Laurie, T. Werner, Limited, London.

Handbook of Physiology. By W. D. Halliburton, M.D., LL.D., F.R.C.P., F.R.S., Professor of Physiology, King's College, London. Eleventh edition (being the twenty-fourth edition of Kirkes' Physiology). Price 15*s.* net.

Notes, Short Comments, and Answers to Correspondents.

ZANZIBAR AND PEMBA.

IT is stated in the annual report of the British Vice-Consul (Mr. Beak) that the population of the islands of Zanzibar and Pemba was estimated to be on Dec. 30th, 1911, 197,199, made up of 234 Europeans, 8305 Indians and Cingalese, and 188,660 of other races. Births numbered 1567 in 1910, 1814 in 1911, and 1535 in 1912; the deaths were 3534 in 1910, 3330 in 1911, and 4255 in 1912. In connexion with the apparent excess in the number of deaths over births, it is surmised that, although the registration of births is compulsory by law, the natives constantly evade the regulations. It should also be mentioned that during 1912 an outbreak of cholera accounted for 900 deaths. The outbreak in question lasted from August to December. Possibly the cholera, which was of a virulent type, was introduced from Bombay, where the disease was epidemic in May, 1912. Perhaps the most disturbing feature of the population statistics is the rate of infantile mortality, which for the town of Zanzibar was 288 per 1000 in 1910, 162 per 1000 in 1911, and 193 per 1000 in 1912 A great deal of this loss of child life, which is possibly the gravest question facing any African administration to day, is due to ignorance and neglect on the part of mothers, and is consequently preventable. An examination of the death returns shows that the diseases which claim the greatest number of victims are tuberculosis (15 9 per cent. of the total), debility (14 0), malaria (13 3), diarrhœa and dysentery (10 2), bronchitis (7 0), dementia (5 4), and anæmia (5 2). During the last few years, although the number of native deaths from malaria has remained practically stationary (the average monthly number of deaths in 1912 was 14 2, as against 15·08, the average for the last six years), and although mosquito borne diseases are still responsible for 25 per cent. of the total admissions to hospitals, and for 9 per cent. of the total attendances at dispensaries, considerable progress has been made in the sanitation of the town and with the drainage of some swamps and the kerosening of others Consequently there has been a corresponding improvement in the health of Europeans During 1912 a severe outbreak of small pox occurred at Mombassa, but Zanzibar escaped very lightly. This escape may be attributed to the fact that 60,000 of the Zanzibaris had recently been vaccinated.

THE USE OF COLOUR IN BOOKBINDINGS.

To the Editor of THE LANCET.

SIR,—I do not know for certain what are the factors which govern the colour of the binding of any particular scientific work, but *would like to suggest that if it is possible a little* method should be introduced into the choice. If all works of "medicine" could be bound in blue, all those of "surgery" in red, all those of "chemistry" in green, and so on, the arrangement of books and the discovery of information would be much assisted If those in authority in the medical profession met the publishing trade on this matter, surely an innovation which would be a benefit to the busy practitioner and to the librarian, and which would prevent the present riot of colour which is observable to anybody with a moderately sized library, would be introduced. Sometimes it is particularly annoying to have two books on diametrically opposite subjects of the same size and shape, and the same colour binding, as the twins will not always keep in their respective departments. I should like to see this classification applied to books on many other subjects—e g., all French dictionaries of one colour, all German dictionaries of another colour, all Spanish dictionaries of another, and so forth.

I am, Sir, yours faithfully,

London, Sept 24th, 1913. BOUQUINEUR

*** The use of colour as a help to systematic arrangement is unduly neglected, but no rules of the sort suggested by our correspondent would be kept by publishers or authors who placed the value of conspicuousness unduly high What an advertisement for both it would be to be responsible for—say—*the only* mauve biology.—ED L.

SUGAR AS A PRESERVATIVE OF BUTTER

AT the Liverpool police court recently a case was heard in which exporters of butter from Cork were charged upon a summons for selling butter containing cane or beet [illegible] it. Analysis showed that 1 2 per cen[illegible] sample upon which the prosecution w[illegible] the defendants was to the effect that to preserve butter sufficiently for market purposes 6 or 7 per cent. would have to be used. Salt was present in the sample to the extent of 4 per cent, a usual amount, and the defendants stated that they had used sugar to the extent proved for 35 years, and that other traders did the same. It was also stated that sugar was used in French butter and in Danish. The stipendiary magistrate, after discussion, dismissed the summons on the ground that the presence of the sugar used with salt as a preservative was not an infringement of *"the Act of 1887," apparently the Margarine* Act, 1887. We have failed to gather from the report before us the precise offence with which the defendants were charged, but we point out that in the case of offences under the Sale of Food and Drugs Acts, by Section 1, Subsection 7, of the Sale of Food and Drugs Act, 1899, "An article of food shall not be deemed to be adulterated by reason only of the addition of any preservative or colouring matter of such a nature and in such quantity as not to render the article injurious to health." We do not see that any evidence was given as to any injury to health likely to result from about 1 per cent. of added sugar in such an article as butter.

THE PSYCHOLOGY OF "DAMN."

IN a recent article in the *Westminster Gazette* discussing the propriety and frequent use of the word "damn" on the stage the writer *remarks "there can be no doubt about the fact that swearing in some* form gives relief to the feelings and acts in a manner similar to that of a safety valve; it is for the physiologist to tell us why." Explanations are many, but none is simple. The emotion of anger in its varying forms, if at all intense, must find an outlet, and its intensity *is often relieved by being first concentrated and then suddenly* dissipated through weeping, the use of expletives, or in other ways. When an expletive is used it may range from the mild feminine "bother" to some coarse sexual expression on which the theory of Freud may throw light; it is generally a *monosyllable* or a dissyllable with the *accent on the penultimate* and the initial stress strongly pronounced. Just as cramped muscles are relieved by "stretching," so emotion may be relieved by focussing it, so to speak, into a verbal expression the first part of which is uttered with concentrated explosive force. We have heard of a man who, finding the effort of restraint from relieving his feelings before his wife somewhat difficult, discovered with much delight the word "baldañ," which we believe represents the adverb "soon" in a certain artificial language. This innocent word served his purpose equally well with the word "damn," suggesting that it is the sound of the word that is effective rather than the sense. This innocent profaner explained that he was helped by what he called the "sonorous rotundity" of the word, but if the analogy with "stretching" is correct, it is merely an example of the law of action and reaction carried into the field of the emotions and the line of least resistance is taken to bring about relaxation for the pent-up feelings. The particular word used by individuals is probably the result of imitation, and once a word is found useful for the purpose it becomes automatically and habitually adopted. Of course, there are people whose temperaments are such that they have little or no difficulty, whether by nature or training, in suppressing the emotional feeling, but for the many, perhaps the majority of men and women, some form of expletive, if used decently and in order, may be excused occasionally. But however elaborately we explain the psychology of expletives their use is a confession of weakness—this must be remembered.

MEMORIAL TO A MEDICAL MAN.

AN interesting ceremony took place on Sept 21st at Bad-Nauheim, when the monument to Dr. Frederick Bode was unveiled and dedicated to the public by the Kurdirecteur, Colonel von Frankenberg Dr Bode was one of the first to recognise the qualities of the Nauheim waters, and did much by his writings to bring the place prominently before medical men and the public.

MEDICAL AFFAIRS IN SOMALILAND

ACCORDING to the annual report prepared by the Acting Commissioner (Mr. G F. Archer), the estimated population of this British Protec-[illegible]

is chiefly remarkable for its very dry character. In the interior it is healthy, generally speaking, throughout the year, but the same can scarcely be said of the coast belt. Here, during the "kharif"—i.e., the months of July, August, and not infrequently half September—the atmospheric conditions are very trying for Europeans, and the effect on the nervous system is most pronounced Terrific gales of dust-laden wind are then prevalent, and the heat is intense, with the thermometer registering 105°—110° F in the shade at midday, and seldom falling below 100° at night. Most of the sickness, however, occurs during the months immediately preceding and immediately following the "kharif." During the months of November, December, January, and February the *climatic conditions on the coast greatly* improve.

A general hospital is situated at each of the three principal towns—Berbera, Bulhar, and Zeyla. At Berbera there is accommodation for 42 beds, at Bulhar for 4, and at Zeyla for 6. Camp hospitals, constructed of matting huts erected on wooden frameworks, have been in use at each of the towns for meeting an epidemic of small pox. These huts have been added to as requirements have demanded; they answer their purpose very well and [illegible] the wind far better than the tents used formerly. The number of admissions to the hospitals during the past year was 592 and the deaths 12, exclusive of 787 cases, with 236 deaths, from small-pox treated at the small-pox camps. There is a dispensary attached to each of the hospitals, and the attendances during the year totalled 47,658. A small room is available at the hospital at Berbera for the purpose of blood examinations, urine testing, &c. No culture equipment exists, but microscopic sections can be cut and mounted and simple chemical analyses conducted.

INSANITARY HOUSES IN MARYLEBONE.

Mrs. Potter, of Salisbury-street, Lisson-grove, was ordered to abate a nuisance and pay 2 guineas costs at Marylebone police-court recently in respect of seven houses, known as East Cottages, belonging to her. The evidence of Dr. E. F. W. Bywater, deputy medical officer of health, showed that the houses each contained eight small rooms, and were each occupied by four, five, or six families, four or five persons occupying some of the rooms. Roofs and gutters were defective, rain soaked through into the rooms, the drinking-water was contaminated, the windows were defective, rats abounded, and the backyards were receptacles of sewage matter. The whole condition of the seven houses was declared by Dr. Bywater to be dangerous and injurious to health. It is to be hoped that as a sequel to the order which he has been successful in obtaining the disgraceful state of affairs disclosed may be put an end to.

FREE MEDICAL ADVICE AT KHARKOFF.

IN his report for the past year the British Consul (Mr. Blakey) at Kharkoff observes that there was no epidemic, but that infectious diseases were, as usual, chronic. An improvement is expected in two or three years' time when the drainage of the town is complete. Public hospitals are short of funds, overcrowded, and quite unable to cope with their duties. A slight relief will be given by the new workmen's sick fund law, according to which 12,000 workpeople of the town will be treated at the expense of the employers. The town boasts of a number of competent medical men, and it is very usual for them to give advice free to the poor. Unfortunately many patients who are well able to pay take advantage of this and pay nothing. In Russia it is not etiquette for doctors to make charges or send in accounts except for surgical cases. The fee is regarded theoretically as a free-will recognition of good services. The making up of prescriptions and the preparing of compounded drugs are in the hands of apothecaries, who must be distinguished from chemists, and their prices, though fixed by the administration, are high. Chemists are more numerous than apothecaries. Chemists trade in cosmetics, simple drugs, patent medicines, &c. The sale of patent medicines is largely on the increase, partly because of the greater cost of medicines made by doctors' prescriptions and partly through energetic advertising.

MESSRS. E. MERCK'S ANNUAL REPORT.

WE have received a copy of Merck's annual report which records the principal pharmacological advances for the year 1912. The present issue is the twenty-sixth volume of the series, and, like its predecessors, fully maintains its scientific character as a source of reference on the latest pharmaceutical chemistry and therapeutics. The section on Preparations and Drugs is preceded by an excellent account of the chemistry and pharmacology of lecithin. We understand that a limited number of copies is being sent to members of the medical profession on application to the London Office, 66, Crutched Friars, E.C.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1913:—

April 25th–Nov. 5th (Ghent).—International Exhibition.
May 31st to October (London, Earl's Court).—Imperial Services Exhibition.
May–October (Leipzig).—First International Building Exhibition.
June–October (London, Crystal Palace).—Anglo-German Exhibition.
Oct. 1st–Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition.
,, 28th–Nov. 1st (London, Royal Horticultural Hall).—Twenty-fourth Universal Cookery and Food Exhibition.

In 1914:—

April 14th–18th (New York).—Fourth Congress of the International Surgical Society.
May 1st–Nov. 1st (Lyons).—International Town Life Exhibition.
Aug. 3rd–8th (London).—Sixth International Dental Congress.
,, 10th–15th (St. Petersburg).—Twelfth International Congress of Ophthalmology.
Sept. 7th–12th (Berne).—International Congress for Neurology, Psychiatry, and Psychology.
September (Vienna).—Third International Congress for Diseases of Occupation.
(London).—Anglo-American Exhibition.
(Aberdeen).—Eighty-second Annual Meeting of the British Medical Association.
(Auckland, N.Z.).—Australasian Medical Congress.
(St. Petersburg).—Third Mendeléeff Congress of Pure and Applied Chemistry and Physics.
(Washington, D.C.).—International Congress of Americanists.
(Paris).—Fourth International Medical Congress on Industrial Accidents.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—T. Watts Eden, C. Hubert Roberts): at 8 P.M.

Opening Remarks by the President, Dr. W. S. A. Griffith.

Specimen:
Dr. Macnaughton-Jones: Pyosalpinx of Accessory Tube.

Short Communication:
Dr. Macnaughton-Jones: Case of Complete Absence of the Internal Genitalia.

Papers:
Dr. Frances Ivens: Report of 26 Cases of Adnexal Tuberculosis.
Dr. Williamson and Dr. Mackenzie Wallis: The Serum Diagnosis of Pregnancy, with a Demonstration of Apparatus and Methods.

FRIDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, D'Arcy Power): at 5 P.M.

Professor Morris Jastrow: Babylonian Medicine.

All Members of the Profession, including Students, whether Fellows of the Society or not, are invited to attend this meeting.

CLINICAL SECTION (Hon. Secretaries—W. Essex Wynter, Thomas H. Kellock): at 8.30 P.M.

Dr. J. D. Rolleston: Case Illustrating Local Treatment of Vincent's Angina by Salvarsan.

And other Cases.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. Davis: Clinique (Skin). 5.15 P.M., Lecture:—Dr. F. Langmead: Some Points in the Treatment of Goitre.

TUESDAY.—4 P.M., Dr. E. Pritchard: Clinique (Medical). 5.15 P.M., Lecture:—Mr. F. A. Juler: Squints.

WEDNESDAY.—4 P.M., Mr. H. A. T. Fairbank: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. D. Sommerville: Gastro-intestinal Maladies and Skin Diseases.

THURSDAY.—4 P.M., Dr. E. Wynter: Clinique (Medical). 5.15 P.M., Lecture:—Dr. A. Latham: Malignant Diseases of the Lung.

FRIDAY.—4 P.M., Dr. D. MacKenzie: Clinique (Ear, Nose, and Throat). 5.15 P.M., Lecture:—Dr. H. C. Miller: Clinical Psychology—2. The Scope and Limitations of Psychic Treatment.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Mr. B. Harman: Diseases of the Eye. Dr. Simson: Diseases of Women.

THURSDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Armour: Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. Mr. Pardoe: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—Out-patient Demonstrations:—10 A.M. Dr. Singer: Medical. Mr. H. Curtis: Surgical. 12 noon, Mr. G. N. Biggs: Throat, Nose, and Ear.——2.15 P.M., Mr. W. Turner: Surgery. 3 P.M., Mr. W. Turner: Operations. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.15 P.M., Mr. R. Lake: Ear and Throat.

TUESDAY.—Out-patient Demonstrations:—10 A.M., Dr. G. Holmes: Medical. Mr. Cole: Surgical. 12 noon, Dr. H. MacCormac: Skin.——2 P.M., Mr. L. McGavin: Operations. 2.15 P.M., Mr. R. Carling: Surgery. 3.15 P.M., Dr. G. Rankin: Medicine.

Dr. F. Lang-
Mr. R. B.
Mr. Choyce:
3.15 P.M.,
C. Choyce:
Surgery.

THURSDAY.—Out-patient
Medical. Mr. H. C
Throat, Nose, and

A.M., Dr. G. Holmes:
Dr. H. MacCormac:
ations. 2.15 P.M., Sir
M., Mr. L. McGavin:
Surgery.

SATURDAY.—Out-patient Demonstrations: 10 A.M., Dr. F. Langmead: Medical. Mr. C. Rowntree: Surgical. 11 A.M., Mr. R. B. Bickerton: Eye.——10 A.M., Col. Harry: Radiography.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY AND FRIDAY.—3 30 P.M., Clinical Lectures:—Dr. G. Holmes: Regional Diagnosis.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

TUESDAY.—6 P.M., Dr. W. Griffith: Parasitology of the Skin.
THURSDAY.—6 P.M., Dr. M. Dockrell: Essentials, Clinical and Pathological, to the Diagnosis of Diseases of the Skin.

MANCHESTER ROYAL INFIRMARY (MANCHESTER HOSPITALS POST-GRADUATE CLINICS).

WEDNESDAY.—4.30 P.M., Dr. G. R. Murray: Chronic Infective Endocarditis.

ANCOATS HOSPITAL (MANCHESTER HOSPITALS POST GRADUATE CLINICS).

THURSDAY.—4.30 P.M., Dr E. B. Leech: Liver Cirrhosis.

MANCHESTER ROYAL EYE HOSPITAL (MANCHESTER HOSPITALS POST-GRADUATE CLINICS).

FRIDAY.—4 30 P.M., Dr. J. G. Clegg: Subjective Tests for Visual Acuity.

ROTUNDA HOSPITAL POST-GRADUATE COURSES, Dublin.

For further particulars of the above Lectures, &c., see Advertisement Pages.

METEOROLOGICAL READINGS.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1913, which was completed with the issue of June 28th, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1913 are now ready. Bound i carriage extra.

Cases ers are also ready. Cloth, g *d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do *not* reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. *CHARLES GOOD, THE LANCET* Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The following journals, magazines, &c., have been received:—*American Post-Graduate, Albany Medical Annals, Archives of Internal Medicine, Bristol Medico-Chirurgical Journal, Indian Medical Gazette, Journal of Tropical Medicine and Hygiene, British Journal of Children's Diseases, Patrician, Revue de Gynécologie, American Journal of Tropical Diseases and Preventive Medicine, Quinzaine Thérapeutique, Journal of Nervous and Mental Disease, Interstate Medical Journal, Journal d'Urologie, Archiv für Experimentelle Pathologie und Pharmakologie, Tropical Diseases Bulletin, Journal of State Medicine, Ophthalmoscope, Review of Neurology and Psychiatry, &c.*

Communications, Letters, &c., have been received from—

A.—Ardath Tobacco Co., Lond.; Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.; Dr. Edward von Adelung, Oakland, California; Argyle and Bute Asylum, Lochgilphead, Secretary of; Anglo-American Pharmaceutical Co., Lond.; *The Abolitionist*, Lond.

B.—Messrs. Burroughs, Wellcome, and Co., Lond.; Messrs. Bale, Sons, and Danielsson, Lond.; Bristol General Hospital, Secretary of; Mr. F. E. Beddard, Lond.; Bad Nauheim Municipal Enquiry Office, Lond.; Messrs. Bruce, Green, and Co., Lond.; Messrs. Butterworth and Co., Lond.; Mr. S. L. Bhatia, Cambridge; Messrs. Benger's Food, Manchester; British Oxygen Co., Lond.; Messrs. T. B. Browne, Lond.; *Blackburn Times*, Manager of; Bristol Royal Hospital, Secretary of; Mr. Victor Bonney, Lond.; Mrs. Cloudesley Brereton, Lond.; Messrs. Baillière, Tindall, and Cox, Lond.; Messrs. Boulton and Paul, Norwich; Beckett Hospital, Barnsley, Secretary of; Messrs. A. Burbidge and Co., Lond.; Miss Alice Browne, Lond.

C.—Mr. Harold Collinson, Leeds; Sanitätsrat Dr. Eugen Cohn, Berlin; Mr. Caballero, Lond.; Messrs. J. and A. Churchill, Lond.; Mr. H. Ley Clark, Lond.; Messrs. Constable and Co., Lond.; Clayton Hospital, Wakefield, Hon. Secretary of; Cheltenham General Hospital, Secretary of; Messrs. E. Cook and Co., Lond.; [illegible] Upper [illegible] Can[illegible] Secretary of.

D.—Mr. A. J. D'Souza, Lond.; Professor Delépine, Manchester; Mr. Edward D. Davis, Lond.; Mr. R. Dunstan, Paignton.

E.—Dr. A. M. Elliot, Lond.; Lieutenant-Colonel R. H. Elliot, I.M.S., Lond.

F.—Messrs. Ferris and Co., Bristol; Dr. W. H. Fitzgerald, Hartford, Conn.; Messrs. Fairchild Bros. and Foster, Lond.; *Farm and Home*, Lond., Editor of; Mr. T. R Freeman, Monkton Combe; Dr. J. B. Farmer, Gerrard's Cross.

G.—Mr. Cecil Graham, Lond.; General Medical Council, Lond., Registrar of; Goodwyn Institute, Memphis, Librarian to the; Guardian Assurance Co., Lond.; Mr. H. S. Gettings, Wakefield; Messrs. Gordon and Gotch, Lond.

H.—Mr. C. R. Haines, Godalming; Dr. Æneas Henderson, Southport; Messrs. C. J. Hewlett and Son, Lond.; Harrogate Hydropathic Co., Manager of; Messrs. Hoskins and Sewell, Birmingham; Sir John P. Hewett, Elgin; Mr. W. H. Hey, Manchester; Mr. T. Harling, Blackburn; Mr. C. W. Hutt, Brighton; Mr. John Howell, Cheltenham; Dr. William Hunter, Lond.; H. B. L.; Harveian Society of London, Secretary of; The Hutcharm Co., Victoria, B.C.; Hospital for Sick Children, Newcastle-on-Tyne, Secretary of; Hereford County and City Asylum, Burghill, Clerk to the; Miss E. M. Homersham, Lond.; Mr. Charles T. W. Hirsch, Woolwich.

I.—International Plasmon, Ltd., Lond.; *Indian Medical Record*, Calcutta.

J.—Miss E. M. Johnstone, Virginia Water; Mr. H. W. Jackson, Lond.; Prof. Morris Jastrow, Philadelphia.

K.—Messrs. H. S. King and Co., Lond.; Miss M. Kordik, Lond.; Messrs. Kutnow and Co., Lond.; Mrs. Kinnings, Fareham; Kensington Dispensary, Lond., Secretary of.

L.—Mr. J. E. Lane, Lond.; Dr. C. Lillingston, Gorleston-on-Sea; Leicester Guardians, Clerk to the; London Press Exchange, Secretary of; Leicester Borough Mental Hospital, Humberstone, Medical Superintendent of; Dr. P. W. Latham, Dalbeattie; Captain R. B. Lloyd, I.M.S., Calcutta; Mr. H. K. Lewis, Lond.; Messrs. Leach and Son, Wisbech; Life-Saving Devices Co., Chicago; *L'Hygiène*, Paris, Editor of; Surgeon-General Sir Charles Pardey Lukis, K.C.S.I., Lond.; Messrs. Hunterian Lecture

ON

FEVER IN PULMONARY TUBERCULOSIS:

ITS SIGNIFICANCE AND THERAPEUTICAL INDICATIONS.

Delivered before the Hunterian Society on Oct. 6th, 1913,

BY FRANK J. WETHERED, M.D. LOND.,
F.R.C.P. LOND.,

PHYSICIAN TO THE MIDDLESEX HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

IN the first place I have to thank you, Sir, as President, and the council of this society for the honour you have done me in asking me to deliver this lecture. When your secretary, Dr. O. K. Williamson, conveyed your invitation to me, he suggested that I should choose a subject which had a distinctly clinical bearing. I warmly accepted the suggestion, so that I shall only touch very briefly on theoretical considerations, and shall make my observations of as practical a character as possible.

The subject of pulmonary tuberculosis has during the last few years attracted much notice from medical practitioners and laymen. Attention has been mainly concentrated on the afebrile cases, as these naturally yield better results, whatever the form of treatment that may be adopted. Consideration of febrile cases has not been so fully entered into, and I have therefore selected as my subject Fever in Pulmonary Tuberculosis: its Significance and Therapeutical Indications. I shall place a liberal interpretation on the word "fever," taking it to mean any rise of temperature. My endeavour will be to place before you the deductions which may be drawn from a study of the temperature chart from the points of view of diagnosis, prognosis, and treatment.

THE CAUSE OF THE FEVER IN PULMONARY TUBERCULOSIS.

The cause of the fever in this disease has led to much discussion. Fever has been described as a disturbance in the relationship between heat production and heat dissipation, and in pulmonary tuberculosis the balance is very easily disturbed. The tubercle bacilli themselves or their products are thrown into the blood stream, usually resulting in increase in body temperature. Some observers, as Dr. F. M. Pottinger, consider fever to be a result of the protective reaction of the body cells in response to the formation of chemical substances, probably the products of autolysis (albumoses). This question I do not propose to dwell upon this evening.

The occurrence of auto-inoculation, to which I shall refer later, has also given rise to differences of opinion. In certain cases of pulmonary tuberculosis, exertion, physical or mental, but especially the former, is followed by a rise of temperature [illegible] r symptoms, such as [illegible] nce is forthcoming to [illegible] of bacteria or their products from the disease foci, and uncontrolled bad effects may follow, as after an excessive dose of tuberculin; on the other hand, good results may ensue, corresponding to the administration of an appropriate dose of tuberculin, leading to the conclusion that an auto-inoculation results from the production of a substance similar to tuberculin and possessing similar properties.

The products of organisms other than tubercle bacilli have been supposed to be responsible for the temperature in some cases of pulmonary tuberculosis; in other words, that a secondary or even mixed infection exists. Some observers have maintained that the temperature chart would indicate when such an infection is present, but I do not believe such is the case. Dr. A. C. Inman,[1] superintendent of the Brompton Laboratories, carried out a valuable research for the Local Government Board, and showed that from the temperature chart alone the presence or absence of a secondary infection could not be determined. Moreover, because micro organisms are found in the sputum in addition to those of tubercle, it does not follow that they play any part in the pathological process that is proceeding. Dr. Inman demonstrated by means of the opsonic index that in many cases, although several varieties of micro-organisms were present, the indices to some of them were normal, thus showing that there was no evidence of infectivity in respect to those particular microbes. The conclusion generally arrived at is that although undoubtedly existing in certain stages of the disease secondary infections have much less effect on the course of the disease than was at one time supposed. Tuberculosis of the lungs is essentially an infection by the tubercle bacillus.

THE SIGNIFICANCE OF THE TEMPERATURE CURVE.

I now turn to more clinical details. I would first observe that throughout this lecture, when I speak about temperature, I refer to the mouth temperature, which for clinical purposes I have found perfectly satisfactory. Attempts have been made to classify the temperature curves occurring in pulmonary tuberculosis on a rather too definite basis, but although certain types may be described, yet there is no curve characteristic of the disease. On looking at the temperature chart of a case of typhoid fever, or croupous pneumonia, the nature of the disease can be fairly easily surmised, but such is not the case with tuberculosis of the lungs. Speaking generally, a raised temperature is a sign of activity, provided that it is continuous. It may be continually above the normal, or there may be rises late in the day only, and the higher and more sustained the curve the greater are the active processes going on in the lungs. The reverse, however, does not hold good, and activity may be accompanied by a low or normal temperature; the prognosis in such patients is almost invariably bad; this phenomenon usually indicates a lack of power of response on the part of the body. This low temperature is occasionally seen after a period of fever, and unless this fact be remembered false hopes of improvement may be raised, for the fall may mean that the fatal ending is approaching

Further, I would like to point out that the temperature is no guide to the stage of the disease, using the word stage in reference to pathological changes. There may be only a comparatively small area of lung affected and very slight physical signs over the lung, yet the temperature is high and shows large daily variations. In some such instances the disease may run a downward course throughout, finally ending in death, the destruction of lung tissue rapidly proceeding. I think such cases are most common in young female subjects from about 18 to 25 years old. On the other hand, extensive lesions may be present in the lungs, cavity formation being well marked, yet the temperature be of a favourable type. In these cases excessive auto-inoculation is not proceeding, although the disease is advanced from a pathological point of view. The immediate prognosis is by no means necessarily bad, and many patients show marked improvement under treatment, and are even able to return to work. These cases demonstrate in a marked manner that in order to form a definite and accurate opinion of a case it is absolutely necessary to study and observe every aspect of the case over some period of time; symptoms, temperature chart, and physical signs must all be considered together and in relation to each other, for to base a diagnosis or prognosis on one aspect only will assuredly lead to error.

Types of Curve in Acute Cases.

There are two types of fever indicative of acute disease which are common, and to which I should like to draw your attention. Before describing these I would first remind you of the variations which occur in the temperature chart of healthy individuals; 98·4° F. is accepted as the normal, but, needless to say, this point does not prevail during the whole 24 hours. There is a daily variation of from a degree to a degree and a half, being lowest in the early morning, and generally highest in the afternoon. It is the amount of variation in the temperature chart of a patient suffering from pulmonary tuberculosis to which I wish to draw your attention; and the observation of this swing yields useful information whatever may be the actual height of the temperature.

In a case of active pulmonary tuberculosis of moderate severity we sometimes find that the temperature is sustained above the normal (Fig. 1); that is to say, the morning temperature is raised as well as that of the afternoon and evening, but the daily variation is not greater than in the normal curve. Under suitable treatment the fever often subsides, and the disease follows a favourable course. In the majority of these cases the disease is limited in extent, and there is but little softening of the lung tissue. In the second type the temperature is again sustained at a high level, but the daily range is greater than in a normal curve, perhaps two to two and a half degrees of oscillation (Fig. 2). On examination of the patient there will then be found indications that softening and excavation are proceeding. As a rule the larger the extent of lung involved the greater becomes the swing of the temperature; the record may become low in the morning and high later in the day, rising as high as 104° or 105°. Severe clinical symptoms often accompany this type of fever, indicating profound intoxication brought about by the absorption of toxic matters—chilliness, amounting to rigors, aching in the limbs, digestive disturbances, and great weakness. The aspect of the patient is also characteristic—marked flushing of the cheeks and a general lassitude and rapid breathing, which at once attracts attention. The second of these types is the more common, but a combination of the two types occurs more frequently than either alone. Similar to this curve is the one sometimes alleged to indicate the existence of a mixed infection. I have already referred to this subject and stated the reasons for the opinion that no evidence of such an infection can be drawn from the temperature curve.

---

[1] THE LANCET, April 13th, 1912, p. 975, et seq.

Other Types of Temperature Chart.

The temperature chart of a slightly active case of pulmonary tuberculosis is very different. (Fig. 3.) The temperature is only slightly raised, and there may be periods in which the curve is almost normal. Nevertheless, at intervals the swing is greater than the normal. In many cases, although the temperature never rises above the normal, yet the daily variation is 2° or more. It will be found that patients with this type of curve often make but slow progress, and great care has to be observed with regard to the daily amount of exercise. This lability and irregularity of the temperature curve is one of the most important early evidences of tuberculosis of the lungs.

There are two other types of curve which are worthy of notice. In the one, the temperature is raised a degree or a degree and a half every afternoon or evening (Fig. 4), becoming normal in the morning. In the other a larger swing is noticed (Fig. 5), the rise later in the day being over 100° F., reaching the normal again in the morning. The immediate prognosis in the former is usually fair; in the latter it is not so good, but the second type may gradually assume that of the first, indicating improvement in the patient's condition.

Another interesting type of curve is that of constant variations in temperature following upon increasing exertion. (Fig. 6.) The patient, perhaps, has been kept in bed until the temperature has become normal. Then he is allowed up for a couple of hours and a rise of temperature occurs. It may fall in 24 hours. Another rise is often seen when the patient is allowed up for four hours, again when six hours are permitted, and so on. Further, the excitement and incidental exertion of a visiting day, or the physical examination by the physician may be similarly indicated. In some cases, however, a fall does not take place in 24 hours, and a febrile temperature persists for some time—perhaps as long as three weeks or more—before a favourable curve again appears. A similar rise of temperature may occur after extraction of teeth or some unusual exertion, such as playing the piano. It is striking that the exciting causes are nearly always associated with some form of bodily exertion.

Whilst discussing pulmonary disease associated with high temperature of long duration, I would point out what may lead to diagnostic error—namely, that malignant disease of the lung may be accompanied with fever. (Fig. 7.) During part of the course of malignant disease of the lung the differential diagnosis may be by no means easy. Naturally, if tubercle bacilli are found in the sputum the diagnosis becomes evident. If the cutaneous or other tuberculin test be employed. further confusion may arise if a positive reaction is obtained, for this simply means that the individual has had a tuberculous infection, but it does not prove that the lung trouble is of a tuberculous nature. The true nature of the disease can often not be definitely diagnosed until a late stage, when enlarged glands in the neck or external tumour reveal the real nature of the malady. I need hardly remind you that there are other conditions, such as bronchiectasis, fœtid bronchitis, and so on, all of which may be associated with fever and need careful differential diagnosis from pulmonary tuberculosis.

The inverted type of temperature, the morning point being higher than the evening, is usually to be regarded as of serious import, although the curve need not be high. A case illustrative of this was that of a girl, aged 19, who apparently made good progress in the Brompton Hospital. She gained weight and her temperature was never above 99°, but it was of the inverted type. She was sent to the sanatorium at Frimley, but it was found useless to keep her there, as the slighest amount of exercise caused auto-inoculation which could not be controlled. Her subsequent progress was unsatisfactory.

Precautions necessary to ascertain the True Temperature.

In order that the true temperature occasioned by the disease may be ascertained certain precautions must be observed. Some of these will at once suggest themselves. A little time should be allowed to elapse after a meal, especially if the temperature is to be taken in the mouth. A slight rise is fairly common after a meal, and an interval of at least half an hour should therefore be insisted on. Again, the temperature should never be taken until an hour after exercise. In normal individuals an appreciable rise frequently takes place after exercise, but quickly subsides; the same events will occur in tuberculous cases, provided that excessive auto-inoculation has not taken place; if such has happened the temperature may remain raised for some hours or days. Further precautions are necessary in the case of patients who are able to take baths, whether hot or cold, sufficient time being allowed for the regulation of the subsequent change of temperature. The time of year also may have an influence, especially in debilitated and wasted patients, the temperature being depressed in cold weather and raised in hot. This, of course, particularly applies to mouth temperatures.

Another matter to which I wish to refer is a rise of temperature that sometimes precedes or accompanies the menstrual period. (*Fig. 8.*) *The rise may amount to several* degrees. Occasionally cough and other symptoms may become more pronounced during this time. Unless this periodical fever is recognised, a false idea of the temperature curve may be obtained. Especially is this likely to occur when tuberculin is given for diagnostic or therapeutical purposes. If a dose should be given shortly before the period the natural rise may be mistaken for a tuberculin reaction.

Amongst other conditions which may cause temporary rises of temperature in tuberculous subjects, apart from the course of the disease, are the occurrence of an ordinary "cold," probably the result of an infection by one of the catarrhal organisms, and an attack of gout. This affection, however, is rare in patients suffering from tubercle of the lung. The occurrence of hæmoptysis is often followed by fever, and this may be of important prognostic value. If the rise only lasts a few days no undue anxiety need be felt, but if the fever persists it may mean a very serious condition—namely, the rapid spread of the tuberculous process in the form of miliary tuberculosis, which proves rapidly fatal. (Fig. 10.)

THERAPEUTIC INDICATIONS.

Having pointed out some of the conclusions which may be arrived at from a study of the temperature curve in relation to diagnosis and prognosis in cases of pulmonary tuberculosis, I now wish to offer a few remarks as regards the therapeutic indications which may be derived from the same source. When the temperature is high, and especially if it continues for a long period, there is a natural desire to try to artificially reduce it, but whether this is always a wise proceeding is open to doubt. The most favourable temperature for the growth of the tubercle bacillus is about the normal temperature of the body, and it is possible that the existence of fever may to some extent prevent, or at any rate inhibit, the multiplication and activity of the organisms. Moreover, it has also been maintained that phagocytosis is more active, and the other defensive properties of the blood more developed, when a moderate degree of fever is present. Unless, therefore, a [illegible] maintained for some time active attempts [illegible] the temperature are not called for. But the prolongation of fever must be a strain

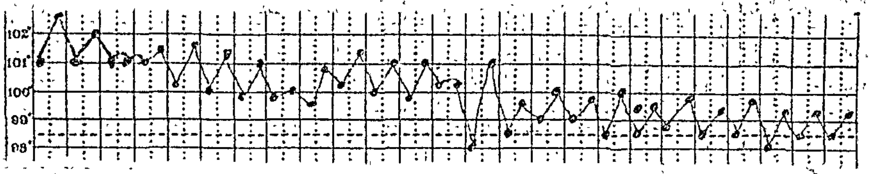

FIG. 1.—Showing sustained temperature with small oscillations. Early lesions at both apices. Patient made good progress.

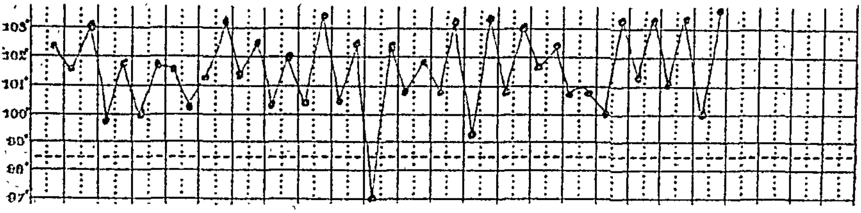

FIG. 2.—Sustained temperature with large oscillations. Active lesions in both lungs. Disease ran an unfavourable course.

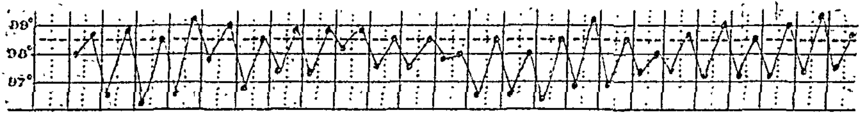

FIG. 3.—Slight activity. Infiltration of both lobes of left lung. No improvement manifested. Patient was not able to take active exercise.

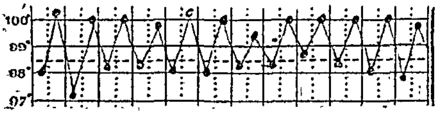

FIG. 4.—Sho
falling eac.
left lung.

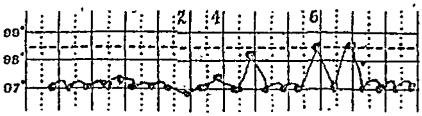

FIG. 6.—Illustrating auto-inoculation. The patient had a limited area of infiltration at the left apex. The figures refer to the number of hours out of bed.

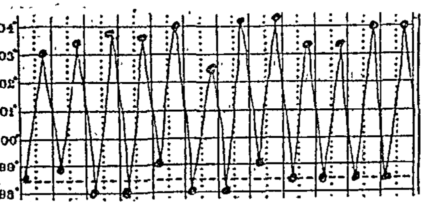

F nperature falling each morning both lobes of left lung and Unfavourable course of disease.

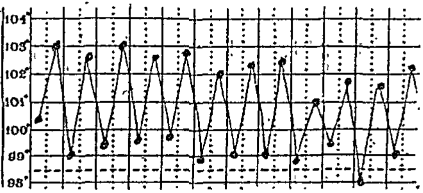

FIG. 7.—Chart of a case of sarcoma of lung.

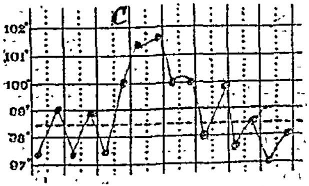

FIG. 8.—Showing rise of temperature during the menstrual period. Menstruation commenced on the day marked C. Patient had advanced lesions in upper lobe of both lungs.

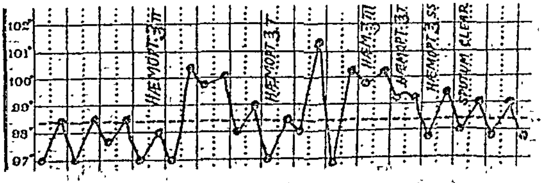

FIG. 9.—Effect of hæmoptysis on temperature. The patient had slight infiltration of the apex of the upper lobe of the right lung.

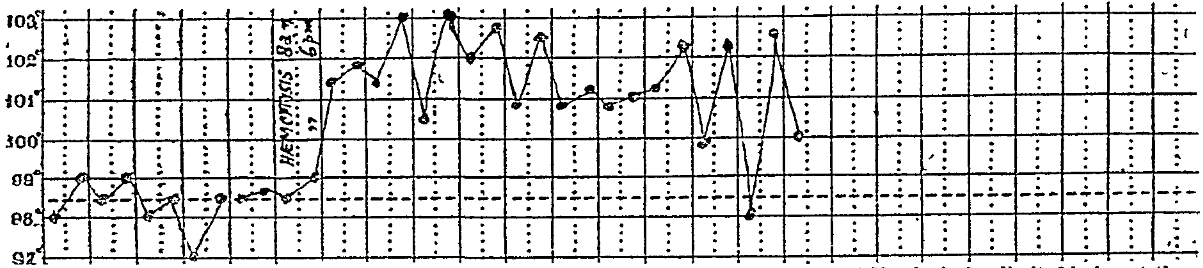

FIG. [illegible] berculosis of lungs. The patient was a man, aged 22, who had a limited lesion at the ape [illegible] e was progressing favourably and able to go out into the garden. An attack of hæmopty [illegible] the lungs which proved fatal in ten days.

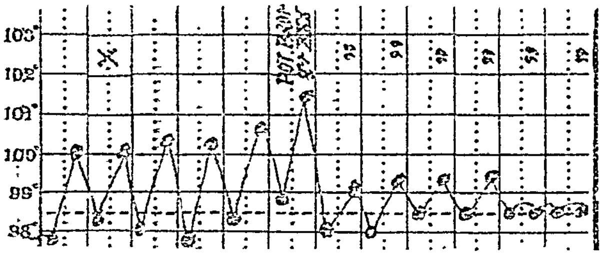

FIG. 11.—Effect of potassium bromide on the temperature in a neurotic patient. There was limited infiltration at the right apex.

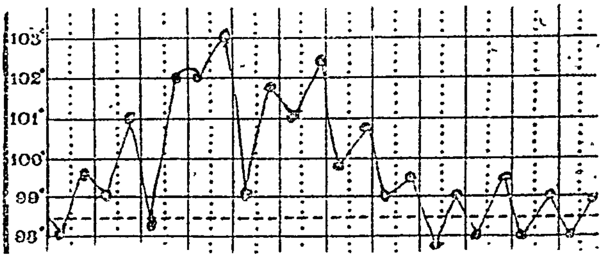

FIG. 12.—Showing the effect on temperature of rest. The patient had excavation in the upper lobe of both lungs.

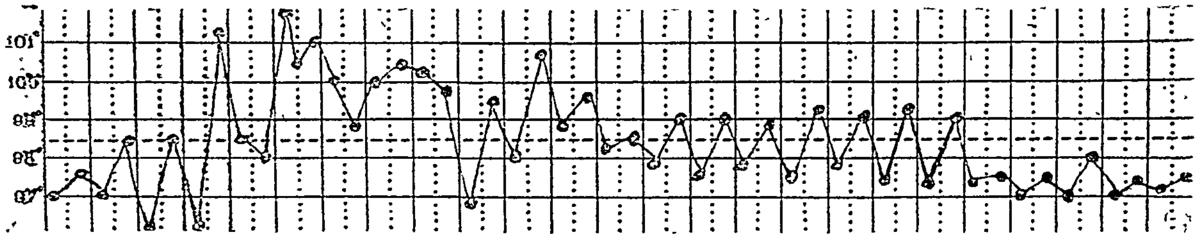

FIG. 13.—Showing patient on work which caused large auto inoculation. He was sent to bed but not treated on the lines of complete immobilisation. Temperature did not settle for a considerable time. (From Dr. M. Paterson's work on Auto-inoculation in Pulmonary Tuberculosis.)

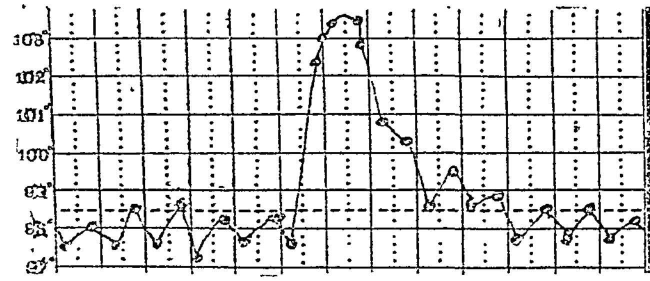

FIG. 14.—Chart of a patient at work which caused large auto-inoculation. He was placed on complete immobilisation and returned to work within ten days. (From Dr. M. Paterson's work.)

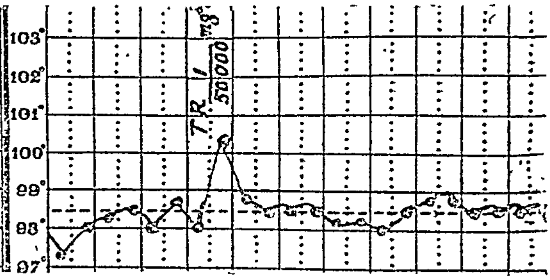

FIG. 15.—Showing febrile response to small doses of tuberculin followed by flattening of the curve. Patient had limited infiltration at right apex.

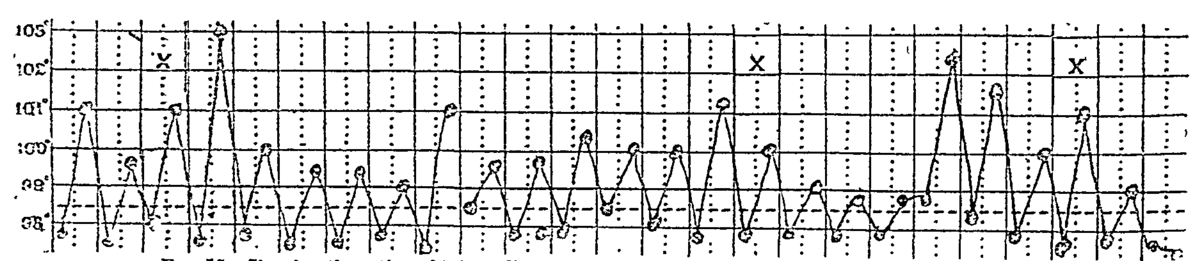

FIG. 16.—Showing the action of tuberculin in a febrile case. X marks injection of T.R. 1/200,000 mg.

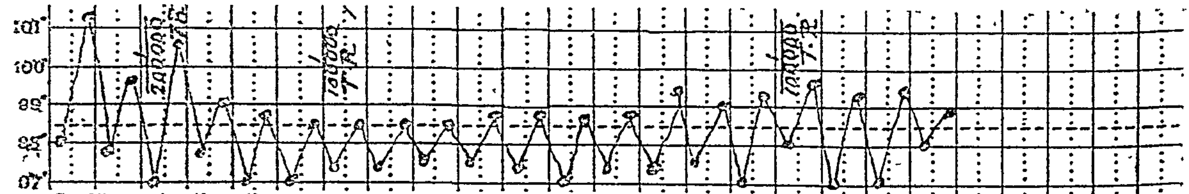

FIG. 17.—Illustrating the action of tuberculin in controlling auto-inoculation. The patient had a limited area of infiltration at the right apex. He was kept at rest until his temperature became normal and then allowed up for two hours and sustained a severe auto-inoculation. The irregular temperature lasted 14 days, the last three days of which are shown. Tuberculin was then given, and after successive doses the temperature became normal. He was ultimately able to be up all day and made good progress.

on the patient's strength, and therefore in some circumstances it may be desirable to try to lower the fever. Many drugs having antipyretic properties have been suggested. In the course of years I have made trial of several, but success has not been great.

The drug to be preferred, according to my experience, is pyramidon; it is claimed to be an amido derivative *of antipyrin. The dose is from* 5 to 8 grains, but patients tolerate the drug differently and respond to it in a varying manner. In some instances 5 grains given in cachets at night have proved sufficient, whilst in others 5 grains three times a day have been required. As a rule the drug is well borne, and depression has only occasionally occurred. In some cases excessive perspirations were noted. With cryogenin I have had no success. It *may be given in doses* of 7 to 10 grains in cachets about three hours before the maximum daily temperature is reached. I have not found the smaller doses produce much effect, while the larger ones have been attended by profound depression. *Phenacetin* and antipyrin I have not given in recent years, although some time ago I tried phenacetin fairly often, but the depression outweighed any advantages the temporary lowering of the temperature might have had. I believe, however, most physicians will agree in the opinion that in the majority of cases antipyretic drugs are not to be recommended. In some patients who are of a strongly neurotic disposition the temperature is very easily affected, and the curve may be irregular, even although the individual is kept at rest as far as possible in bed; under these circumstances the administration of bromides will be found efficacious. (Fig. 11.)

The Value of Rest in Febrile Cases.

A very different agent and far more reliable is rest. The importance of keeping a patient at rest during the active stage of the disease cannot be over-estimated. By this means auto-inoculation may be checked, and thus bacteria and their products are not thrown into the circulation. The period during which rest must be enforced naturally varies with individual cases. Sometimes a short period suffices (Fig. 12), but frequently some weeks or even months may be required. Under the latter circumstances great perseverance is necessary on the part of the patient, but experience shows the reward which follows patience and fortitude. Even apparently hopeless cases after a long period of rest begin to show *improvement, but unfortunately, on the other hand,* in spite of all care and patience, many cases pursue an unfavourable course from the outset. Rest should be insisted on until, in men, the temperature does not rise above 99° in the 24 hours; in women 99·2°, or even 99·4°, may be allowed. When the curve has maintained this level for four to six days, the patient may be allowed to get up for two hours and sit in a chair, and then the next day he can try moving about his room, the rest of the day being spent on a couch instead of in bed. If the circumstances of the patient permit it, he can be carried into the open air or lie on a couch, properly protected from cold, in front of the window. The time for getting up and the amount of exercise are then gradually extended, careful watch being kept on the temperature chart for any undue rise.

In cases which do not respond to these measures, and in which the patient has been allowed to sit up in bed and perform certain acts for himself, such as washing, writing, and so on, "absolute" rest may be tried. The patient is then treated as though he were suffering from typhoid fever, with the exception, of course, of the diet. He must not be permitted to do anything for himself; he must lie "like a log." He must be fed by the nurse, and must not make any voluntary effort whatsoever. The bed-pan, of course, must be used, and the patient is sponged down and must not wash himself. The visits of friends must be discouraged, *and he should talk as little as possible. The beneficial effect* of this treatment is especially marked when there has been severe auto-inoculation. Dr. Marcus Paterson who was for some years medical superintendent at the Brompton Hospital Sanatorium at *Frimley*, and who elaborated the "graduated labour treatment" for pulmonary tuberculosis, found in the early days of his administration that when a patient exceeded the instructions that were given him, he occasionally received a severe auto inoculation the effects of which lasted from two to three weeks. These effects were fever (Fig. 13), headache, loss of appetite, and sometimes pain in the side. The temperature was frequently raised for the length of time I have stated and subsequently some little time elapsed before the patient could again engage in the "grade" of labour at which he broke down. If, however, on the appearance of the symptoms the patient was placed on "absolute" rest, the temperature and the other symptoms subsided in a much shorter time (Fig. 14), and he could be speedily restored to the former grade of work. The return to the ordinary movements of everyday life has to be carefully supervised; in fact, as Dr. Paterson has himself expressed it, there must be graduated rest as well as graduated labour.

From my own experience I have *not* found absolute rest so successful when I have applied it to progressive cases with persistent fever, although I have frequently prescribed it. The fact that uncontrolled auto-inoculations have been occurring continuously and that the pathological process is actively extending explain the difference in the action of this measure in the two classes of cases. The diet during "absolute rest" should be given in as convenient a form as possible, as the patient ought to be fed, but "slop" diet is *not necessary. Solid* food may *still* be given unless symptoms of indigestion manifest themselves.

To secure the required rest drugs may sometimes be of assistance. It will be found that patients who have a very severe cough often exhibit a raised temperature. The effort of coughing, especially if prolonged for a considerable time, naturally entails considerable physical exertion, with the result that auto-inoculation follows. If a sedative cough mixture be given, so that the patient is able to obtain actual rest, then a more favourable temperature may be obtained. For the relief of these severe paroxysms of coughing I have found the linctus sedativus of the Brompton Hospital Pharmacopœia as efficacious as any preparation. The composition is: *Liquoris morphinæ acetatis, min.* viii.; ætheris chlorici, min. iii.; succi limonis, min. xv.; mucilaginem acaciæ ad fl. drm. i. One drachm to be taken when the cough is severe. Codeina or omnopon may also be tried, but I have not found them superior to the morphia preparation. Sponging with tepid water may be tried, but it only gives very temporary relief.

The Administration and Dosage of Tuberculin in Febrile Cases.

When rest and the ordinary drugs fail are there other methods at our disposal? Can tuberculin help us under the circumstances? Some authorities maintain that fever is a direct contraindication to the use of this remedy. I cannot support this view in its entirety. I would rather say that fever is an indication for the most careful administration of tuberculin, but does not absolutely forbid its employment. When treating afebrile cases with tuberculin it is difficult to form any definite criterion as to its effect; we may observe the reactions, but the actual effect on the course of the disease cannot easily be determined. In order to arrive at an absolute conclusion a large number of cases must be dealt with and must be watched for at least five to seven years. *Pulmonary tuberculosis is a disease* which tends to self-arrest; a large number of patients who are afebrile show improvement under ordinary routine treatment, and it is difficult to prove, because a case of this kind becomes better *under* the use of *a* certain *remedy, that therefore the* improvement is due to the action of that remedy. In judging of the progress of those afebrile cases treated with tuberculin, a further difficulty or source of error is added—namely, failing to distinguish between a tuberculin and a tuberculosis immunity. With febrile cases, however, the circumstances are rather different, for the effect of a remedy is more speedily apparent. For some years I have largely confined myself to the use of tuberculin in febrile cases, and I have met with a certain amount of success, and with the doses I employ I have never found any ill effects follow. When *I first* used the *remedy* on patients who had a raised temperature I allowed the patients to remain from three to six weeks in the wards in order to ascertain whether rest and the ordinary methods of treatment would produce good *effects. Under the term "ordinary* methods" I of course include life as far as possible in the open air or well-[illegible] If at the [illegible] ot become [illegible] *need.*

The choice of the particular preparation to be used naturally requires care. Some of the patients had fairly extensive lesions, and it was important, therefore, to employ a tuberculin and in such doses which, whilst exerting an immunising action, would not produce a focal reaction. Koch's old tuberculin (O.T.) or perlsucht tuberculin (P.T.O.) would not be suitable, as they produce such a reaction; tuberculin residue (T.R.) or bacillary emulsion (B.E.) can bring about an immunising effect when given in small doses without focal reaction. I therefore invariably employ one of the two last named, and have obtained similar results with each, but if I have any predilection it is in favour of B.E.

The dose that should be employed in febrile cases must be extremely small. My usual initial dose is 1/100,000th mg.; sometimes 1/200,000th mg. After a dose is given a few days should be allowed to elapse in order to ascertain whether any result follows. If the temperature chart indicates no change after five to seven days the same dose is repeated. If there is then no change, or if no febrile reaction follows, a dose of 1/50,000th mg. should be administered, and another interval of five days allowed to pass; if there is no change another dose of 1/50,000th mg. is given. The same procedure is repeated with 1/25,000th mg. and 1/20,000th mg. If no lowering of the temperature is achieved by these means, or, in other words, if the same grade and type of fever continue, I think it is better not to proceed with the tuberculin.

If after the initial dose a rise of temperature occurs, the dose should not be increased; in fact, it is advisable to lower it. It is not usual to obtain a febrile reaction with such small doses, but that reactions do occur occasionally under these circumstances is shown by the accompanying chart. (Fig. 15.) If, however, after the initial dose there is a fall of temperature or flattening of the curve, another dose should not be given until the temperature begins to swing again. The interval then required between the doses varies, the principle being not to give another dose until the effect of the former one has passed off; this is shown by the temperature beginning to oscillate. The dose is then increased, and again the variation in the temperature is noted, giving a third and increased dose when a renewed swing takes place. With regard to the sequence in the strength of the doses of tuberculin it is better to feel one's way carefully in the febrile cases, treating each patient in regard to the clinical state, the manner in which there is any or no response to the injections, and regulating the doses and intervals between the doses accordingly. At the same time the pulse must be noted, undue frequency necessitating a smaller dose and slower progress. The manner in which tuberculin acts in febrile cases is shown in the accompanying chart. (Fig. 16.) I am strongly in favour of avoiding febrile reactions if possible. The response I prefer to see is a flattening of the curve. (Fig. 15.)

Results of Tuberculin Treatment.

The results I have obtained with the use of tuberculin in febrile cases have varied considerably, but I can say that I have not found these minute doses productive of any harm, and the conclusion I have arrived at is, that when the temperature does not fall after a rest of some weeks under favourable surroundings tuberculin may be administered in the manner I have indicated, and in some instances it will be found efficacious in reducing the fever and in effecting general improvement. To express the matter in other words, the administration of tuberculin occasionally appears to produce an immunising effect sufficiently strong to turn the unfavourable course of the disease into a more favourable one. I am afraid the number of cases in which success is obtained is not large, but nevertheless I do consider that it is a remedy which is well worth giving when other measures have failed, provided that there are no direct contra-indications. If the patient is obviously exhausted by extensive lesions of the lungs, or if there is evidence of rapid disintegration of lung tissues, it is evidently useless to try to obtain an immunising response. The pathological condition is such as to forbid any such treatment. Also, if the type of temperature and physical signs point to miliary tuberculosis (Fig. 10), tuberculin must not be administered.

In some of the cases of pulmonary tuberculosis the effect of the tuberculin is different; it acts as an antipyretic, but has no effect on the course of the disease. The temperature is lowered and a tonic effect is produced, the patient feeling better after each injection, but the progress of the pathological processes is not checked. The length of time that the antipyretic action is continued varies, but it is usually short; nevertheless, it is well to give the remedy on account of the temporary relief which it affords to the patient.

The class of febrile cases in which tuberculin yields the most satisfactory results is that in which the patient is free from fever whilst at rest, but in which a rise of temperature occurs when exercise is taken. This may otherwise be expressed by saying that whilst the patient is at rest no auto-inoculation takes place, but when he gets up and attempts to walk, then auto-inoculation does occur. Tuberculin given in small doses apparently renders him immune to any dose of toxin which he himself can manufacture. I show the chart (Fig. 17) of a case of this nature which well illustrates the beneficial action of tuberculin. By persevering with the treatment a patient, who at first could not be up for two hours without a severe auto-inoculation, is able to be up without fever. Tuberculin has now accomplished its object, and the case may be treated as an afebrile one. The procedure to be adopted is similar to that just described in the case of persistently raised temperature, the initial dose being usually 1/100,000th mg. B.E. The same reduction of temperature sometimes occurs as a result of subjecting the patient to suitable slight movement, such as allowing him to get up for two hours. The explanation of this apparently anomalous phenomenon is the same as applies to the action of tuberculin in febrile cases.

The question of mixed infection has already been discussed, and the idea has naturally been expressed that possibly a vaccine prepared from one or more of the other organisms present might be of value. So far the results obtained have not been altogether encouraging in advanced cases. In less severe and suitably selected cases diminution of fever and in the amount of expectoration appears to have been obtained, with definite relief to the patient.

Conclusions.

From a review of the above considerations it may be assumed that a rise of temperature, apart from accidental factors, may be considered an indication of activity, and that the most reliable means for reducing activity is rest. If, therefore, a patient who has been progressing favourably exhibits a rise of temperature, it must be accepted as a sign that rest must be insisted on. In other words, a patient suffering from pulmonary tuberculosis must live in accordance with his temperature chart. Any increase of cough and expectoration, headache, general malaise, and so on, should always be regarded as calling for a record of the temperature for a few days, and should a rise be found the necessary measures should be taken in accordance with the general features of the case.

In conclusion, I have to offer my sincere thanks to my house physician at the Brompton Hospital, Dr. A. S. Hahn, for the great assistance he has been to me in searching for suitable temperature charts for illustrating my remarks; and, finally, to reiterate that [illegible] lecture my aim has been not to give a [illegible] on the factors which produce fever in pulmonary tuberculosis, but to offer some suggestions which I trust may be of value in actual practice.

ROYAL SANITARY INSTITUTE.—The provincial sessional meeting of this institution will be held on Friday and Saturday, Oct. 17th and 18th, at Newcastle-upon-Tyne. On the first day there will be a meeting in the council chamber of the Town-hall at 7.30 P.M., when a discussion will be opened by Professor H. J. Hutchens, D.S.O., bacteriologist to the Newcastle-upon-Tyne corporation, on Some Points in the Relationship of Human to Bovine Tuberculosis; and Dr. S. J. Clegg, assistant medical officer to the borough, and Mr. William Hudspeth will open a discussion on Housing Problems in a Northern Industrial Town. Among those who have promised to take part in the discussion are Sir Thomas Oliver, Dr. T. M. Allison, Dr. H. Renney, and Dr. E. M. Smith. Dr. Philip Boobbyer will preside. On the following day there will be a short demonstration of the new electrolytic treatment of industrial lead-poisoning, a visit to lead works, and a survey of the housing reconstruction scheme at Forth Banks. After luncheon visits will be made to places of local interest. Tickets may be obtained from Dr. H. Kerr, medical officer of health of Newcastle-upon-Tyne, and of the secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W.

An Introductory Address

ON

EXAMINATIONS, EXAMINERS, AND EXAMINEES.

Delivered at the Opening of the Winter Session at St. George's Hospital Medical School on Oct. 1st, 1913,

BY SIR WILLIAM OSLER, BART., M.D., F.R.S.,

REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD.

GENTLEMEN,—In every department of human knowledge men are asking guidance in the solution of a world-old problem—how to train the mind and heart and hands of the young. The past and the present are in the melting pot—the moulds are ready, and all await with eagerness the result of the casting, and none with greater eagerness than our own profession. For we are in a quandary. Naturally conservative, we are bewildered by the rapidity of a forced *progress and change. There is a new outlook in every* department—not alone in the fundamentals of science and in methods of practice, but in the relations of the profession to the public and to the State. The actual care of the sick, once our sole duty, is now supplemented by such a host of other activities, social, scientific, and administrative, that an ever-increasing number of our members have nothing to do with patients as such. But the chief difficulty is the extraordinary development in every subject of the curriculum—a new anatomy, a new physiology, a new pathology, new methods of practice, to say nothing of phenomenal changes in physics, chemistry, and biology. Everywhere increased complexity and mind-burdening terminology. What is the teacher to do! And more important, What can the poor student do, confronted with so much new knowledge and a Rabelaisian onomatomania? How simple was a cell in the days of Schwann and of Schultze—nucleus, nucleolus, *protoplasm, and cell membrane; to day in* one of the very briefest of recent descriptions I counted 40 new names, not one apparently superfluous Turn to the index of a new treatise in embryology, to a work on immunity, or [illegible] will appreciate the [illegible] the modern student. [illegible] le, and to read intelligently an article in the *Zeitschrift fur Chemotherapie* or in the new archives dealing with immunity and metabolism requires a special education.

The truth is, we have outrun an educational system framed in simpler days and for simpler conditions. The pressure comes hard enough upon the teacher, but far harder upon the taught, who suffer in a hundred different ways. To help you to realise this pressure and to suggest measures of relief are the objects of this address.

EXAMINATIONS AND THEIR RELATIONS TO EDUCATION.

What a student knows and what he can do—these are judged by examinations, oral, written, and practical. Tests of progress, tests on behalf of the public of fitness to follow certain callings, they have always loomed large in educational systems. At the best means to an end, at the worst the end itself, they may be the best part of an education or the worst—they may be its very essence or its ruin. Helpful if an integral part of the training, they may, and do, prove the intellectual ruin of many good men. Long practice as an examiner—year by year since 1875—in many subjects, in many methods, and in many places, an intimate relation with a large body [illegible] education give me [illegible] of experience. M[illegible] mediæval tradition of the omniscience of the professor, and with my brother Regius of Cambridge I enjoy the rare privilege of examining in every subject in the curriculum, from organic chemistry to obstetrics, a privilege with this advantage—it enables me to see the work of many examiners.

Regarding examinations, I have one question to ask—Are they in touch with our system of education? and one suggestion to make—That from the day he enters the school, in laboratory, class-room, and wards, the work of the student should count, and count largely, in the final estimate of his fitness.

The Influence of Examinations on Medical Education.

Apart from a general feeling of dissatisfaction with the present system, two things strongly suggest a negative answer to the first question. As a discipline of mind and memory examinations play a leading part in all educational schemes. How they may finally control and sterilise the mind *of a nation may be read in the story of* China. For this has come about, not from lack of brains, not from any failure to appreciate the value of learning, not from any defect in the system itself, which is more rigid and exacting than anything in Western life, but from the blighting influence of an education directed to a single end, the passing of examinations. To test an education by its practical results at the table is to sin against the spirit of the Greeks, who first taught the fundamental lesson that the pursuit of knowledge to be productive must be disinterested. Nothing is more fatal to a true intellectual training than a constant preoccupation with its practical results. To be of any value an education should prepare for life's work. To train the senses for observation and the mind for reasoning, and to acquire a knowledge of the human machine and its disorders, a man spends five or more years at a medical school. Given a knowledge of the sciences on which it is based *there is no more fascinating study, since medicine is* the only one of the great professions engaging equally head and heart and hand. In its subject matter there is everything in its favour, and it is the easiest possible thing to carry out John Locke's primary canon in education—arouse an interest. With our present methods there is scarcely a subject which cannot be taught easily, and so many of them are practical, manipulative, and not at all difficult to acquire. To an inquisitive mind the study of medicine may become an absorbing passion full of fascinating problems, so many of which present a deep human interest. In the long category of man's conquests none are more brilliant than those with which a teacher of medicine can inspire his class. It is hard indeed to name a dry subject in the curriculum. And yet in an audience of medical students such a statement nowadays raises a smile. Why? Because we make the examination the end of education, not an accessory in its acquisition. The student is given early the impression that he is in the school to pass certain examinations, and I am afraid the society in which he moves grinds this impression into his soul. Ask *at* what he is working, and the student will answer *for* his first M.B. or his final. The atmosphere is Chinese, not Greek, and too often the one aim is to get through. We have become quite shameless about it, and practically admit a failure in our teaching when we advertise special tutorial classes for the different examinations, and *consign a large proportion of our pupils to the tender care* of "grinders"—and to no purpose! The spirit is taken out of instruction, and teacher and taught alike go down into the valley of Ezekiel—where they stay among the dry bones.

The Number of Rejections.

And a second circumstance proclaims loudly how out of touch are our tests with our teaching. The qualifying examinations of this country are well organised and admir*ably conducted, and, speaking by the book,* I may say that nowhere is the knowledge that a man can use so freely tested in the laboratory and at the bedside. And it has been so for several generations, yet year by year the General Medical Council issues a report that gives any teacher food for serious thought, as it demonstrates, beyond peradventure, how completely out of touch he or the student, or both, has got with the examiner. A medical school is a human factory, turning out doctors as the finished product at the end of five years of careful *preparation and fitting of the mental* machinery. Failure is incidental to every human effort, and even the Rolls-Royce Company turns out cars from their shops that fail in the tests, but not many: But from our shops, after five long years or even more, we send our medical motors to be tested for the road by the official experts, and nearly one-half are declared to be defective and sent back to the shops. Use and Wont, those "grey sisters," have so dulled the edge of this bitter experience that we have become accustomed to *conditions nearly insupportable.* Year [illegible] the returns in the two great final [illegible], easiest to teach, show [illegible]

To the question much thoughtful attention has been given, and in the General Medical Council so far back as 1896

Mr. Pridgin Teale introduced a motion with the following preamble: "That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student but damaging to medical education." Mr. Teale pleaded wisely and forcibly for a reduction of the examinations and for the substitution in certain subjects of certificates from the teachers and class examinations.

The Council reports show that the percentage of rejections at the final examinations has progressively risen from 12·4 in 1861 to 22·2 in 1876, to 34·8 in 1886, and to 41·9 in 1895. Mr. Teale, who quotes these figures, remarked that with the multiplication of examinations the more fatal do they become. The figures for the five years 1908 to 1912 show a continuation of the upward movement. Take the great final subjects, medicine and surgery, at the three Boards before which we may say the average student presents himself. I will put the collected figures as concisely as possible. The English Board: medicine—passed 1842, rejected 1135, percentage 38·12; surgery—passed 1821, rejected 1506, percentage 45·23. Scotland: medicine—passed 489, rejected 653, percentage 57·18; surgery—passed 492, rejected 731, percentage 59·77. Ireland: medicine—passed 322, rejected 231, percentage 41·77; surgery—passed 326, rejected 239, percentage 42·30. In the five years a total of 4572 students were examined at the Conjoint Boards of the three kingdoms in medicine, of whom 2019 were rejected, a percentage of 44·16. Of 5105 examined in surgery 2475 were rejected, a percentage of 48·48. Take for comparison the three universities—Edinburgh, Oxford, and Cambridge—for the five years ending 1912. At the Scotch capital there were 985 examined in medicine, of whom 267 were rejected, 27·10 per cent.; in surgery 974, of whom 317 were rejected, 31·52 per cent. In Oxford, where the three final subjects are taken together, it is impossible to say upon which subject a man came down, but in the final examination of 135 candidates 47 were rejected, a percentage of 34·81. At Cambridge during the five years, in medicine of a total number 519, 365 passed and 154 were rejected, a percentage of 29·67; and in surgery of a total 603, 233 were rejected, a percentage of 38·64.

There is not so much difference, you notice, between what may be called the pass men of the Conjoint Boards and the men entering the universities, and I do not believe there is any special difference in stringency between the Oxford and Cambridge examinations and those of the London Conjoint Board. There are two other examinations which the élite of the student body affect. How do they stand? All regret that in London only the select and the elect attempt to get the degree of their own University. And it is difficult! Twice in the past five years more students have failed than have passed the final subjects for the M.B. The total figures for the period are: of 1061 candidates examined 481 were rejected, a percentage of 41·01. And, lastly, to one other qualification, greatly prized, sought only by the very best men, the Olympic athletes of their classes, I will refer—the F.R.C.S. Eng. Consider, please, how carefully this group is trained—only the very best venture to compete, and they have a diet of which the intellectual calories are gauged with surpassing accuracy. There is no doubt they are our very best, the picked steeple-chasers of our stables. How do they fare? I am almost ashamed to read the figures. Your ears have tingled already, but only those hardened by familiarity will not be shocked at the demonstration of such a chasm between education and examination. Of 1186 men who have tried for the primary Fellowship examination of the Royal College of Surgeons during the past five years 821 were rejected, 69·45 per cent. Of 680 men at the final Fellowship examination 294 were rejected, 43·23 per cent. The high-water mark of examination futility was reached in May, 1912, when of 118 candidates for the primary Fellowship only 31 were approved. These are picked men, our very best students, the most carefully prepared, who rarely attempt the trial without months of extra study and attendance upon grinding classes. Of the ploughed I have known personally, many seem to have been over-trained, others had spent their time in unprofitable original research; but all, passed and plucked alike, I maintain, are of the highest type of our students, whose calamities proclaim to the world the breakdown of our present educational system.

The failure is general all along the line and in all grades—at the licensing boards, at the older Universities of Oxford and Cambridge, at Dublin and Edinburgh, at South Kensington, and at Lincoln's Inn-fields; with singular uniformity all tell the same tale. There have been uneasiness and talk, but too much self-satisfied indifference, and even after the famous rout for the primary Fellowship in May last year I am told that satisfaction was expressed with the scope and method of the examination! Satisfactory to the examiners, perhaps, though I doubt it; but most unsatisfactory to the teachers, most painful to the students, and by no means a pleasure to the public as represented by the parents.

How May Relief be Obtained?

I venture to offer a few suggestions. First, by simplifying the curriculum to give the students more time. Allow the teachers a free hand in the matter of systematic lectures. Let them be reduced to a minimum or abolished altogether. One advantage they have—subjects may be dealt with which cannot possibly be illustrated in the wards. But such may be better presented in the "seminar" form, the senior students arranging the subjects among themselves under a skilled assistant. London students still have too many lectures in medicine and surgery to attend; Scotch students many more. I do not speak without experience when I say that the subject of medicine, for example, may be taught without the set lecture. The lecture has its value, a precious one from some lips—a Watson's or a Trousseau's; but its day has gone, to give place to other methods better adapted to modern conditions. Think of the saving of time if the lecture list was snipped in half, or if the lecture was limited to a few subjects, such as physiology and pathology, and if it were an offence for a senior student to be seen in a lecture-room!

Then let us boldly acknowledge the futility of attempting to teach all to all students. Burn the anatomical fetish to which we have sacrificed long enough, and to our great detriment. Just glance at "Cunningham's Anatomy"—1465 pages, many in small type, not one of which is without a water-jump for the first Grand National of the *medical* student. It is barbaric cruelty with so much ahead to burden the mind with minutiæ which have only a Chinese value—a titanic test of memory. To schedule a minimum of the essentials should not be difficult, once the great principle is acknowledged that in all departments of the curriculum only a few subjects can be mastered thoroughly. I am afraid the secret of the tragic tale I have related *lies in* a quotation which Socrates made to Alcibiades:

> Full many a thing he knew,
> But knew them all badly.

I acknowledge the difficulty of defining in different subjects a minimum of the essential, but it is not insuperable, and such schedules are issued in some universities.

Secondly, relief may be obtained by giving credit for work done throughout the course, changing the present system of "signing up" for one of reports by demonstrators and assistants on the character of the work done by each student. Let all who teach examine. Let education and examination go hand in hand. Let the day's work tell from the moment a student enters the school. Everyone from the junior demonstrator who supervises the student's first dissection to the professor—all should weigh while teaching. Day by day as I see John Smith in the wards, and read his notes, and watch his clinical work and discuss the features of the patients, or as he narrates his case to the class about the bed and he and I have a Socratic dialogue, instruction and examination go hand in hand, and in such a way that at the end the formal tests should be but an amplification, an extension, and an inclusion of the scores of examinations which have been part of the routine of his life. Perhaps at present Utopian, this plan will be feasible in a new and reorganised generation; indeed, it is feasible now in self-contained universities. Once accept the principle that instruction and examination should go hand in hand and the difficulty is solved. The returns are automatically passed on to the head of the department. Yes, but someone will say, "Take the judgment of a group of young teachers? It is absurd!" Not a bit. They see more of the students, come into closer contact, and are better able to judge of the quality of their work than the professor, and much more than any outside examiner. According to the character of his work a student should acquire much or little merit, and should be able to take to the examination table enough to pass, or at any rate to make the final test in any subject *pro forma.* Where the classes are small, as in many of the provincial universities, this plan could be easily worked. I have had practical experience of it and came to the conclusion early that the judgment of the man who was fit to teach could be taken in estimating the progress of the student's education. And the system is being adopted. A few months ago I went into the beautiful clinical and pathological laboratory of the new Toronto General Hospital, and in one room I found an examination in pathology going on. The candidate had a set of cards in his hands, on each of which were written the details of the post-mortem examination he had made with a careful discussion of the case. Pass or pluck really depended on the cards a man held. He brought his marks with him—instruction and examination had gone hand in hand. I was delighted to hear from Professor MacKenzie that the system, introduced at McGill by my pupil and successor, the late much lamented Wyatt Johnston, had proved very successful in both Canadian schools.

Thirdly, simplify the examinations. Cut off some of the written papers. In the final subjects the long report on cases, the bedside *viva*, supplemented if need be by a special "oral," will give examiners the necessary knowledge of a candidate's mental outlook. If they will consider, not how much he knows, but how he knows what he knows, the long "written" is superfluous. As one watches a man handle a patient it is easy to tell whether or not he has had a proper training, and for this purpose 15 minutes at the bedside are worth three hours at the desk. We must substitute for the quantitative estimate the qualitative, and judge the student as much by manner as by matter.

Fourthly, when possible, evidence of original work should be substituted for examination. Think of the stimulus to British surgery if, in place of the Egyptian tyranny to which our best students now slavishly bow, the President and Council of the Royal College of Surgeons selected for the Fellowship each year the 15 or 20 of the men under 30 who had distinguished themselves most highly in surgical research. It would change the mental attitude of the younger generation, instil the spirit of Hunter into its members, and prevent the paralysing mental sterility that overtakes many good men who now spend precious plastic years in the dry drudgery of examination details.

Fifthly, compel no student to pass an examination twice in the same subject. At present brain and pocket alike suffer, and the burden could be lightened by a free reciprocity between the examining boards.

EXAMINERS AND THEIR DUTIES.

Men are usually very superior to the system in which they work, and so it is with examiners. After what has been said you may be disappointed not to hear a tirade against them; but I have had a singularly happy experience with my fellow inquisitors, whom I have found, as a rule, among "the mildest-mannered men that ever scuttled ships or cut throats." The two extreme types, the metallic and the molluscoid, illustrate inborn defects of character. The aggressive, [illegible] and the hard [illegible]" expression, [illegible] it reaches his [illegible]s, perhaps, to a serious mistake in his paper. Imagine the mental state of a poor chap greeted with, "What did you mean by saying that the ciliary muscle is supplied by the pneumogastric nerve?" And the worst of it is that the metallic examiner may have no sense whatever of his failings, but is rather apt to pride himself on a keen appreciation of his duties. I remember a hard-faced inquisitor who took, so it seemed, the greatest pleasure in torturing his victims—dwelling with fiendish glee on all the small mistakes he could find, criticising the spelling, and ending on one occasion with the cheerful remark, "Mr. Jones, who taught you to write?" That evening, talking about examinations, I said in a joking way: "Judge Jeffreys, you are a heartless brute; I wonder some student has not assaulted you." He took it very much to heart, and I had a long letter about the great responsibility of the position and the rigid sense of duty he felt towards the University and the public. And the facial expression of the fellow examiner is not without importance, whether sympathetic, neutral, or antagonistic. One co-examiner always had a sardonic expression, a sort of Arian grin, plainly saying, "Well, you are a hopeless idiot!" The examination room may have the atmosphere of a cold storage chamber, and a student knows at once the type of man with whom he has to deal.

At the other extremity is the invertebrate examiner, so soft and slushy that he has not the heart to reject a man. It is a variety not often met with in this country, but it exists. Sympathy with the student and a strong feeling for his position may completely overmaster the sense of duty to the university and to the public. A former colleague was made unhappy for days if he had to reject a candidate. For some years I sat on an examination board with an elderly professor, a man of great force of character and ability, who never gave a candidate less than 80 per cent. of the possible marks. In the case of the most hopeless duffers with 20, 30, or 40 per cent. in other subjects he would call out "pass." He was a great grief to me, as well as a mystery. At the last meeting which he attended as an examiner he tossed his book to me with a malicious smile. There were 116 candidates, not one of whom he had rejected, and not one of whom had less than 80 per cent.!

Between the metallic and the molluscoid is the large group of sensible examiners who try to put the candidate at his ease and to find out what he knows in a simple, sympathetic manner. But in any case the examiner is apt to take an unfair advantage of his position, and quite unconsciously. A specialist to whom the facts of his subject have become familiar and ingrained is apt to forget the years that have given the facility and the knowledge; and he may wonder when a man hesitates over an Argyll-Robertson pupil or mistakes a pericardial rub for an aortic insufficiency murmur. The most grievous mistake of the examiner is to regard the candidate as his mental equal and to expect from him knowledge of the same quality as that which he possesses, ignoring his long years of study and the short years into which the student has had to cram the knowledge of a dozen subjects.

Examining is often a heart-breaking task, with little to relieve the monotony of the long-drawn papers. It is distressing to meet with abysmal ignorance of elementary facts, and to realise with sorrow how many more minds are constructed as sieves than as sponges. But there are compensations, and who is there among us who does not appreciate Comte's statement that there were few more delightful experiences than the sweet and softened feeling when a young man's examination was thoroughly satisfactory! But it is much nicer to watch the gradual growth of a student's knowledge and to get it out retail day by day than to drag it out wholesale at set times. One thing is certain—the best we have should be devoted to our duties as examiners. Men should give their whole time to the business when at it. Much-engaged men should not be chosen, and to examine in the evening, after a hard day's work, is to handicap the candidates. We shall no doubt come to a time when professional examiners will be appointed by the General Medical Council to act as associates and assessors to the professors. That it is not a task lightly or inadvisedly undertaken the returns I have given indicate only too clearly. Not that we can lay at the doors of the examiners the responsibility for the lamentable state of affairs to which I have referred. No doubt there are unduly severe examinations, and there are examiners with hearts as hard as pieces of the nether millstone, but these are exceptions.

THE EXAMINEE AND HIS POSITION.

When quoting figures I purposely dealt chiefly with the results of the final examinations, and I am sure the feeling uppermost in your minds was one of sympathy with the hundreds of young men who, after five years of hard work, fail in ordinary tests, and this brings us to a brief consideration of the examinee and his position. In two respects he is an unfortunate victim. Of one I have already spoken—the enormous development in the subjects of the curriculum; and here, I am sure, lies his serious difficulty. It is the case of a quart measure and a pint pot. Intellectual dyspepsia from cramming is at the bottom of his trouble. It is like a diet of hot bread, which a man can stand at first, but, as Lowell says in the "Fable for Critics"—

> By gradual steps he
> Is brought to death's door by a mental dyspepsy.

Another cause of the widespread rejections is defective preliminary education; but let me emphasise the fact that the percentages of rejections are nowhere higher than among the very best students—e g., Cambridge men, among whom in some subjects more than 50 per cent. are rejected. I do not deny that much could be done to relieve the present stasis if all medical students began thoroughly trained in physics, chemistry, and biology. In this respect matters are improving year by year. And we should be more honest with the feeble ones, not fitted either by breeding or by pasture to pursue their studies, who should be asked early to withdraw. It is infinitely kinder to stop a man in his career than to allow him to struggle on painfully and submit to the humiliation of half a dozen or more rejections.

The conclusion of the matter is, the student needs more time for quiet study, fewer classes, fewer lectures, and, above all, the incubus of examinations should be lifted from his soul. To replace the Chinese by the Greek spirit would enable him to seek knowledge for itself, without a thought of the end, tested and taught day by day, the pupil and teacher working together on the same lines, only one a little ahead of the other. This is the ideal towards which we should move. The pity of it all is that we should have made an intolerable burden of the study of one of the most attractive of the professions, but the reform is in our own hands and should not be far off. A paragraph in an address of the late Dr. Stokes contains the pith of my remarks: "Let us emancipate the student, and give him time and opportunity for the cultivation of his mind, so that in his pupilage he shall not be a puppet in the hands of others, but rather a self-relying and reflecting being."

An Introductory Address

ON THE

PRESENT PROBLEMS RELATING TO THE ORIGIN OF MODERN RACES.

Delivered at the Opening of the Winter Session in Medicine at the University of Birmingham on Oct. 7th, 1913,

BY ARTHUR KEITH, M.D. ABERD., F.R.C.S. ENG.,

CONSERVATOR OF MUSEUM AND HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

GENTLEMEN,—Less than a month ago the Principal of this University took the members of the British Association a long excursion into space and bade them look on the planet on which they live at such a distance that neither man nor beast was within the limits of sight. Only great structures like the Forth Bridge and the Assuan Dam were visible.[1] To-night I want you to look at the earth a little closer—near enough to see its variegated covering of humanity as its continents revolve under our eyes.

THE WORLD'S CARPET OF HUMANITY.

As the western seaboard of Europe passes by and our own country comes in sight we shall suppose we are near enough to perceive that the human carpet along our Western coast is not quite of the same texture as that which covers the lands sloping down to the North Sea. When Europe itself comes under our gaze the pattern of the human carpet begins to change, and by the time the Far East has risen under the morning sun we shall admit, I think, that the change has become decided. A pall of smoke, the wreckage of a battle-field, the demarcation of new frontiers reveal to us one of the processes at work in modifying the pattern of our carpet. When we turn our eyes southwards and view Africa across the Mediterranean there is at first no marked degree of change—not until the great forest region beyond the Sahara comes in sight. A glance from Northern Europe to Central Africa reveals the extremes in the earth's covering of humanity—not the extremes of material—merely of pattern or design; European and African seem to be products of the same loom. In the southern corner of Africa human contrasts of another kind may catch our eye. We may there see a valiant attempt being made to weave a new human carpet, one in which the European thread of the woof will not intertwine with the African thread of the warp. In this new carpet lie the decaying threads of one of the most remarkable patches to be seen in the widespread covering of humanity—the Bushman and Hottentot tribes.

As Europe and Africa sink out of sight and Asia rolls past under us, we see the human pattern again undergo a change. South of the Himalaya the plains of India are covered by peoples of diverse kinds, in whom we seem to detect a mixture of European and African features. North of the Himalaya a wide part of the earth is covered by men who are quite unlike those already seen elsewhere. The Mongolian type cannot be compounded by mixing other known elements of humanity. South of the Equator—the Asiatic aspect of the hemisphere—in Australia and the islands of the Pacific we may perceive a bewildering mixture of human patterns, varying from the negro type towards the European and also towards the Mongolian. Lastly, the new world unfolds itself. At first sight it seems to present an entirely European complexion. Peering beneath the surface, however, it is easy to see numerous remnants of diverse and ancient races. More than in any part of the earth the web of humanity is being actively woven in the New World. North of Mexico there is a resolute determination to keep the white and black threads separate; from Mexico to Cape Horn nature weaves the human web as she will.

THE PERMANENCY OF HUMAN TYPES.

Having thus followed Sir Oliver Lodge into space and surveyed in a cursory manner the world's carpet of humanity, we shall now return to earth and see what we can ascertain concerning when and how it came to be woven. It is the "when" rather than the "how" which concerns us in the present hour. The belief is still general that it is not many thousand years since the world became populated by the races of modern man. Such a belief is not illogical. When we try to imagine what has happened in the past we must base our speculations on what is taking place under our eyes at the present time. There is a restlessness, a migratory instinct inherent in a considerable proportion of every population. I dare think that in Birmingham there are to be found not only natives of every county of England, but that most of the Welsh, Scotch, and Irish counties are also represented. Birmingham has not only received, it has also given. If it resembles other towns it has sons and daughters throughout the world. The objection will be at once made to this train of reasoning that the migratory tendency alluded to is of recent origin—that it is a result of our modern civilisation. Industrial or individual migration is a new condition, but predatory or collective migration has evidently been in existence as far into the past as history or tradition can take us. Amongst more primitive races of man—and it is they who give us the key to the early state of civilised races—there lurks a deep-rooted tendency to collective migration. When we realise the rapidity with which a people may multiply and the tendency inherent in all human races to migrate, it is conceivable that mankind may have spread from a centre and occupied the whole earth in the space of a few thousand years.

The discoveries which have been made during the last 50 years clearly indicate that the distribution of mankind and their separation into widely different races have not been a rapid but a very slow process. Thanks to the labours of the Archæological Survey of Egypt, to Dr. Reissner, to Professor Elliot Smith, Dr. Wood-Jones and Dr. Derry, we know something of the people who occupied the Lower Nile Valley during the last 8000 years. At every phase of that long period there was found evidence of the arrival of new types—of migrations or invasions of Egypt—but there was also clear evidence of the survival of the old types. There was evidence of mixture, but the final conclusion to be drawn from a study of the ancient inhabitants of the Nile Valley is that the passage of 8000 years left the prevailing human types modified to only a slight degree. Recently Dr. Seligmann has shown that certain native tribes near Suakin on the Red Sea have features and bodies very similar to the predynastic Egyptians. The explorations of Mr. Henry S. Wellcome in ancient cemeteries of the Soudan have demonstrated that the peculiar, tall, slender, long-limbed negro tribes which now occupy the upper waters of the Nile were there at least 2000 years ago. The lesson that Egypt has to teach us is that human types are not easily changed. The explanation which is usually given—and I am prepared to accept it—is that the conditions of life along the Nile Valley have remained unchanged during recent millenniums, thus ensuring the permanency of the human type.

---

[1] THE LANCET, Sept. 13th, 1913, p. 785.

When we turn to America we find farther evidence of the permanence of human types. In recent years Dr. Ales Hrdlicka, of the Bureau of American Anthropology, has written two excellent memoirs on the remains of ancient human skeletons which have been discovered in the New World. Of those discoveries I propose only to cite one—the human skeleton discovered at Lansing, in the State of Kansas, 11 years ago, in a glacial deposit at a depth of 23 feet. Dr. Frederick Wright, who has given a lifetime to the study of glacial deposits in North America, and especially to the antiquity of man in that country, regards the deposit under which the skeleton was found as formed before the last cycle of glaciation, and gives its probable antiquity as about 12,000 years. If the European cycles of glaciation were contemporaneous with those of North America, then the antiquity, if I may infer from the estimates given by our own geologists, is very much greater than has been calculated by Dr. Frederick Wright. No one has ever called in question, no one can call in question, the authenticity of the age of the Lansing skeleton. Dr. Hrdlicka, however, rejects it as representative of ancient man in America on the ground that "this man was physically identical with the Indian of the present time, and that his physical characteristics during all the thousands of years assumed to have passed have undergone no important modification." We see from that statement that Dr. Hrdlicka is under the belief, one which is widely held at the present time, that human types are so liable to variation that it is impossible for them to breed true over a long space of time. We must accept facts as we find them and suit our beliefs to fit our observations. The plain lesson of the Lansing find is that before the last great glacial cycle there existed a type of man in the central States almost identical with the modern Indian of the same region.

THE EARLY PEOPLE OF ENGLAND.

When we come to study the history of our own countrymen we reach a similar conclusion. Our archæologists are opening up Anglo-Saxon cemeteries of the fifth and sixth centuries and revealing to us the physical characters of the people who gave us their language and their blood. Their teeth were better than ours, their limb bones are usually rather different in conformation, but the counterparts of those people are to be seen on every hand at the present day. Every year we come to know more of the people who inhabited Britain in the Roman period; they are the same kind of people as ourselves; their heads showed the same variety of forms as may be seen in Birmingham to-day. When we go further back, to the time before iron was used and weapons were made of bronze—to a date which takes us some 2000 years before the birth of Christ, we find human types with which we are still familiar. Those handsome men with high, rounded heads, whom we now know as squires and men in posts of authority, first appear in our country at this date. They were originally natives of Central and Eastern Europe; they were not a new type of man—only new to England. When we go further back and explore those mounds or barrows which contain the men who lived in England in the Neolithic period we do not find new types; the men of that time, except as concerns the state of their teeth and shape of their limb bones, were at one with us. Five thousand years ago the men of England were of our stature, had the form of head and the strength of muscle which has been given to many of us.

When we pass beyond the Neolithic period to reach the time when only stone implements of the more ancient or palæolithic type were used, we were supposed, until a few years ago, to come to a blank or hiatus in our knowledge. That blank is in the process of disappearing. Recently Mr. Reginald Smith, of the British Museum, has recognised that the flint implements which were left by the men who dug those peculiar pits at Cissbury and in other parts of England were not early neolithic people as is usually supposed, but were in reality palæolithic folk. Now we know some of the skeletons of these early Englishmen; they were men exactly of the common British type. Lately I had an opportunity of examining two discoveries of human remains from Kent which were so similar that they might have been almost members of the same family, yet we are fairly certain that they belong to very widely separated periods. The remains of one set of people were discovered at the base of an ancient stone monument at Coldrum, in Kent, within the valley of the Medway, by Mr. F. J. Bennett, F.G.S. Only worked flints of a neolithic type were found during the excavations; we may, therefore, presume that the people who were buried in the ancient tomb at Coldrum were Kentish people of the Neolithic period. The more ancient skeleton was discovered a short distance from Coldrum, near the little town of Halling, situated on the Medway, a few miles above Rochester. At Halling the Medway is flanked by a terrace of brick-earth, laid down at some previous period, when the Medway flowed a number of feet above its present level. This terrace had to be cut through when a new sewage system was being constructed for Halling. The terrace was seen to be made up of a number of superimposed strata or layers, each layer or stratum being of different composition, and therefore marking a separate period in the action of the river. Beneath the fourth layer, counting from the surface, were found charcoal, charred stones, and remains of hearths, with worked flints which belong, not to the neolithic, but to the palæolithic type. They are similar to those found in the floor-strata of French caves, and are of the type assigned to that palæolithic phase of culture known as Aurignacian. The upper four layers had thus been deposited over an old habitation of the men who lived before the close of the Palæolithic period—who actually were in Kent towards the close of the last cycle of the Glacial period. In the fifth stratum, at a depth of almost 6 feet from the surface, was found a human skeleton, which has been preserved and investigated by Mr. W. H. Cook and Dr. Spencer Edwards. To me it is clear, from the flexed posture of the skeleton, that they were dealing with a burial, but not one made by modern men from the present land surface, but one made from the ancient land surface by the palæolithic men who lived before the last four layers of the terrace had been deposited. A full investigation of the skeleton showed that the palæolithic man of Halling was very near akin to the neolithic people of Coldrum, and yet the years which elapsed between the periods at which the one and the other lived must be counted in thousands. A few miles north of Halling, in the valley of the Thames, is Tilbury. When the docks were excavated an old land surface was reached at a depth of 32 feet; two feet below this old land surface was found the skeleton of the Tilbury man. He belongs to that form of ancient Briton to which Huxley gave the name of "river-bed" type; he is first cousin to the men who have long lived on the shores of the Mediterranean and which Sergi has distinguished as the Mediterranean race. The remains found at Halling and at Coldrum may also be assigned to the river-bed type. This type was not confined to the south-eastern part of England. From the old forest land now submerged along the western and southern coasts of England human skulls of this type have been recovered. The skull found in the Cheddar caves and described by Mr. Davies as belonging to the closing phase of palæolithic culture is of the same class. Some 60 years ago, when a cutting was made for a new railway near Mickelton in Gloucestershire, a skull of this type was found at a depth of 10 feet, beneath peat and undisturbed blue clay—certain indications of a great antiquity. A few years ago the Rev. E. H. Mullins explored a small limestone cave which lies in a narrow valley behind his rectory at Langwith Bassett in Derbyshire. In the cave he found numerous remains of animals—many of them now extinct—and clearly belonging to the geological period preceding the present—the Pleistocene period. He found worked flints and a human skull. The skull was of the river-bed type, but its condition was so fresh that at first I was inclined to think some mistake had been made. Mr. Mullins, however, showed me that the condition of preservation of the skull was exactly the same as that of the bones of the extinct animals. It is probable that the Langwith cave skull is of the same age as the Halling skeleton; both appear to belong to that period of palæolithic culture—the Aurignacian. How long ago it is since the Aurignacian period closed we have as yet no accurate means of judging, but those who have studied the changes which have occurred in our valleys and in our fauna suppose that we must make a liberal allowance of time—30,000 years or perhaps more.

THE ANTIQUITY OF MAN.

We have thus surveyed the history of the men of three parts of the earth over a considerable period of time. In all three places the result has been the same—we see the same persistence of type in Egypt, in America, and in England. In this hall to-night there are representatives of the men of the Derbyshire cave and of the Halling terrace; in America the Red Indian preserves the form of men who lived before the last glacial invasion of North America; the predynastic Egyptian survives in the tribes on the shores of the Red Sea. We may, therefore, suppose that if inquiry were made in China, in India, or in Central Africa the result would be the same—that in Central Africa we could follow the Negro type well back into the Pleistocene period; in China the Mongolian type, and in India the Dravidian. It is when we come to realise the persistency of human types that we see that we must allow a very long period indeed to cover the time needed—not for the population of the world, but for the differentiation of modern man into the well-marked races with which we are all familiar. The characters which separate the European, the Chinamen, the negro impress every one of us; we cannot overlook them. Yet when we come to examine those races structurally we must admit that they are so much alike that we must suppose, to account for their community of structure, that all three have come from a common stock.

The question we have to face in solving the problem of the antiquity of the modern races of man is, How long will it take for the separation of an African, an Asiatic, or a European, from a common stock? It is evident, from what we have discovered concerning the fixity of human types, that it will take a long period—infinitely longer than most modern geologists will allow.

When we approach the problem of the antiquity of man from the side I have tried to present to you, we obtain some assurance that the human beings who represent the common stock from which all our modern races have diverged could not be of a very low type. When we come to study the features which characterise the brains of the various human races—so far as these differences may be detected with the naked eye—we see that they relate to structural details. In their main features they are alike. It is true that a skilled anatomist will, if you show him a representative specimen, distinguish the brain of a negro from that of a European or from that of a Chinaman; I do not think, however, he could tell with any degree of certainty the brain of the Chinaman from that of the European. Seeing that the brains of all modern varieties of men are so much alike in the essential features of their architecture, it is a legitimate inference, I think, that a large and moderately complex brain is a common inheritance of modern races—that in the common stock from which all modern races have arisen a fairly large human brain must have been already present. We, therefore, ought to find even before the differentiation of the present races of mankind that there were human beings in existence with large brain already.

I am now to lead you on to another aspect of this problem which is hotly contested at the present time. In tracing backwards the ancient inhabitants of England, I left off with the remains which are assignable to the later part of the Pleistocene period. I now propose to advance well into that period. In the valley of the Thames there still persist, in the form of a gravel terrace, remnants of an ancient bed of the Thames It is known as the 100-foot terrace because it is situated about that distance above the level of the Thames. About the geological age of that terrace, at least its deeper strata, there is no dispute; it belongs to the earlier half of the Pleistocene period. Now it was in that terrace, at a depth of 8 feet, in strata which contained worked flints belonging to an earlier form of palæolithic culture, and with remains of pleistocene mammals, that the Galley Hill skeleton was discovered. The remains are those of a man of our type. It would not be easy to find his match in our present population; I doubt if anything approaching a counterpart to him could be found, but he could appear in a modern company without his features calling forth any special remark. The remains were discovered in 1888. Some years before a fragment of a human skull was unearthed in a deposit of brick earth near Bury St. Edmunds at a depth of 7 feet. With it were found mammoth tusks and implements of the Acheulean type—a culture which belongs to Middle Pleistocene time. It is only a fragment, but there is sufficient of it to make us certain that the original skull of which it formed part was shaped as in modern human races. Two years ago Mr. J. Reid Moir, of Ipswich, discovered a human skeleton beneath an undisturbed layer of chalky boulder clay 3½ feet in thickness. The skeleton lay in the flexed posture, and probably represented a burial, but it was one made before the chalky boulder clay was laid down. That is a deposit following the great glaciation. The skull and skeleton have the features of modern races, all except the tibia—that was shaped differently to any human tibia I have yet seen. The Ipswich skeleton represents a man of the modern type. Thus, in my belief and in that of many competent men, we have discovered in England representatives of modern man in existence in England, even before the middle of the Pleistocene period.

By Professor Boyd Dawkins and Dr. Smith Woodward such discoveries are regarded as impossible; with Dr. Hrdlicka they think that a human type could not persist from the Mid-Pleistocene to the present day unchanged. In their opinion all the human remains just mentioned represent Neolithic burials. Our Neolithic ancestors took the trouble to dig a grave 8 feet deep in the 100-foot terrace, and laid the strata down again so carefully that we cannot now detect their forgery. The Neolithic men of Bury St Edmunds laid a fragment of a dead man's skull 6 feet deep in brick-earth with mammoth tusks and Acheulean implements to delude a simple set of men in the twentieth century into believing that mankind of our type was ancient!

NEANDERTHAL MAN AND THE PILTDOWN SKULL.

Another obstacle to the belief in the antiquity of our own type of mankind has been removed in recent years. I may describe it as the Neanderthal bogey. A certain school of geologists became obsessed with the belief that it was impossible for any species of mammal to come through a long geological period unchanged, and inferred that man could not escape so universal a law. The discovery of that extraordinary type of mankind over half a century ago—the type which is now known as Neanderthal—confirmed this belief. To a superficial eye Neanderthal man was just the individual wanted to represent our stage in evolution during the Pleistocene period. He had many simian features which we do not possess. We have come to realise now that he had also many high specialisations, and that he cannot stand in the direct line of our ancestry. We know him now as a being quite distinct from all modern races; the difference between him and us is much greater than between a European and a negro; he represents a totally different form of human being. We now know his culture and his period. We have followed modern man right up to the threshold of the period at which he lived; it is also clear that he died out in front of modern man in the same way as the Tasmanian disappeared before the European. Neanderthal man does not represent our Pleistocene ancestor. Where, then, is our pleistocene ancestor if not at Galley Hill, at Ipswich, and at Bury St. Edmunds? These remains were found in older deposits than those which contain the remains of Neanderthal man. In Italy it is the same as in England; human remains of our type have been found, but they have been rejected because they were not of the Neanderthal type.

The remarkable skull which was found at Piltdown by Mr. Charles Dawson and which has been described by Dr. Smith Woodward, is destined to throw a new light on the problem of man's antiquity. It was found in a very shallow deposit, little more than three feet below the surface of the ground. If it had so happened that this skull presented modern characters, what would have been said of it? I am certain that Professor Boyd Dawkins, Dr. Smith Woodward, and Dr. Hrdlicka would have regarded it as a recent burial. If its high degree of fossilisation had been brought to their notice they would have replied that fossilisation was a most uncertain indication of antiquity; they would have cited bones from neolithic burials which show mineralisation to an equally great degree. If it was pointed out to them that the remains found with the skull were those of extinct animals belonging to the Pleistocene period they would have replied that a recent burial may be made in a Pleistocene stratum and bones of different ages thus mingled. I draw your attention to those aspects of the case of the ancestor of modern man—he is sentenced before his trial begins. In the *case of the Piltdown skull*, characters are present which mark its ancient date. No modern man has such a chin or lower jaw; and if Dr. Smith Woodward is right in assigning the canine tooth found at Piltdown to this jaw *no human being has been seen with such a simian canine* tooth. In many features the Piltdown man foreshadows our type. Does he, then, represent our ancestors near the beginning of the Pleistocene period, admitting for the sake *of argument that the Piltdown man is Pleistocene* and not Pliocene in date?

The opinion I have formed is that he does not lie in the direct line of our ancestry. I base my opinion on the fact *that we know of the remains of two different species or genera* of mankind in Europe at the beginning of the Pleistocene period—one is the Heidelberg man, the other is the Piltdown. The Heidelberg man was certainly of the Neanderthal type, *the Piltdown man is much more of our own type.* They are clearly products of a common stock. We must presume, from what we know of man's nearer relatives—the anthropoid apes—that the common ancestor of Piltdown and Heidelberg man *possessed the ledge-like overhanging eyebrow* ridges which characterise the anthropoid forehead. These ridges have disappeared in the forehead of the Piltdown man; they have been retained by Neanderthal man. On the other hand, in the Heidelberg jaw the region of the chin already shows human modifications; the Piltdown man retained the simian form. There is, if we may use Mendel's law for this pu [illegible] mediate descendant of [illegible] ancestor missing—one w [illegible] of the chin and the disappearance of the ledge-like supra-orbital ridge. That missing form would serve well as our ancestor. We *must, then, not dismiss as neolithic burials those human* remains which have neither simian eyebrow ridges nor simian chins. I still maintain, as I did before the discovery of the Piltdown skull was made, that the Pliocene ancestor *of modern man was one probably as highly evolved as the* aboriginal man of Australia.

An Introductory Address

ON

THE PROBLEMS OF UNIVERSITY MEDICAL EDUCATION IN LONDON.

Being the Annual Report of Charing Cross Hospital Medical College presented at the Opening of the Winter Session on Oct. 1st, 1913,

BY W. HUNTER, M.D. EDIN., F.R.C.P. LOND.,

DEAN OF THE COLLEGE.

[Dr. Hunter in the first part of his report briefly reviewed the results of two years' experience of concentration of the earlier medical studies, as adopted two years ago, by transferring its students for this purpose to the University of London, King's College Laboratories, immediately adjacent to the school. The result has been a marked increase in students from a total of 109 in the school in the year 1910–11 to an average of 150 during the past two years. The school is now practically entirely medical, the dental students for the most part having passed to the two or three schools in London which are especially interested in dental education, increasing their prosperity, while this loss to Charing Cross Hospital Medical College has been compensated by a still larger increase in the *number of medical students.* Of [illegible] ore- [illegible] lon. [illegible] by the *concentration* plan, have been devoted to the bacteriological and public health departments of King's College, and the school is enabled to make a grant of £250 a year out of the rent received therefor to the university laboratories. As to the disadvantages attaching to the concentration method, Dr. Hunter knew of none; even the fears of its interference with the social life of the hospital and school have proved groundless, for the interest in the Students' Union and its many spheres of activity and in athletics has never in the history of the school been more active and intense. The *result has justified the* opinion expressed by Dr. Hunter in his last annual report, when speaking of these changes as constituting an experiment in connexion with university medical education, that the new policy meant not "the breaking *up of the school*, but the making up of the school." Dr. Hunter, *in the second part of his* report, went on to deal with the Problems of University Medical Education in London.]

The University of London and the School Hospitals.

Medical Education has been a welcome guest and has had *a free run in all the school hospitals from the* very first. This is in striking contrast to the experience of medical teachers elsewhere—*e.g.*, in *Berlin, the capital of Germany,* where all the hospitals refused to allow students to make use *of them, and early in its career (25–30 years ago) the* Government was in consequence compelled to build the great Charité Hospital of Berlin—*at first for its own war* purposes and *now* maintained for University purposes. Still *more in America up to the present time,* where the greatest difficulties are put in the way of medical schools by the governors of hospitals refusing or limiting their permission for students to attend. In return for their free use by the University, the *hospital governors in London have never* asked or received any material or other recognition from the University.

This freedom of the hospitals throughout the whole history *of English medicine forms the basis of the chief English* clinical traditions of medical education.

[Dr. Hunter here quoted several passages from the evidence of Mr. Abraham Flexner before the Royal Commission *showing that the clinical training is immensely* better in England than in any ordinary school in America, and that in some respects conditions are distinctly more favourable to the student than they are in Germany, concluding with the [illegible] to be nothing here materially [illegible] and particularly with the rela- [illegible] lucation.]

The Great Task of the London Schools in Medical Education.

How great the task of London medical education has been, and still is, is shown by figures and statistics which I placed before the Royal Commission. The medical schools of London, up to as recently as 20 years ago, were responsible for the entire medical education of no fewer than 70 per cent. of the total students of England and for the part-time education of another 10–20 per cent.—of no less than 80–90 per cent of the students in England, this number constituting no less than 42 per cent of the entire students of England and Scotland. Despite the formation of seven provincial Universities during the past 10–15 years, it still has to educate, in whole or in part, over 70 per cent. of [illegible] and over 40 per cent. of the tot [illegible] d Scotland. The medical sch [illegible] ischarged in the past, and still continue to discharge, a big task for English medical education, and they have done this under great and increasing difficulties without endowment and without the slightest pecuniary support from the university whose students they educate. What, then, is the chief *problem* presented by university medical education in London? It is represented to be the hospitals of London—their number, their intense interest in education, their multiple energies, *the difficulty of reconciling their existence* and their energies with the grafting on to them of another system of education [illegible] it is alleged, for the establish- [illegible] howing the defects of the British system from the educationist's point of view—viz., the need for the University to have complete control of its own hospital, to make England a contributing factor of the progress of medicine. Clinical teaching had failed to keep pace with laboratory improvements in medicine, and such productivity as had occurred had been in spite of the system. What was needed was greater prominence for the educational aspect of the training. London hospitals were disorganised as a whole and individually. A reorganised faculty would soon reorganise the wards.]

Here, then, the picture of English medical education as it is drawn by a distinguished American educationist (not a doctor) is sharply outlined. If the shadows are too deep in places and wrongly placed his object is the highly laudable one, beneficial to education, of directing attention to the existence of the picture at all—not necessarily to its completeness or absolute technical accuracy.

The problems facing University medical education in London, as here presented, are thus the following formidable ones: 1. To create, in the first place, a university which will be concerned and *financially able* to give any education at all to its students in their final hospital and school studies. For this the University of London has, so far, never done. 2. To create a *new Senate*, limited in number to 10 or 15 men, with the fullest financial, administrative, and executive control over the whole affairs of the University. 3. To create a new *Faculty of Medicine*—small, compact, and sufficiently business-like in its methods to be able to draw up a scheme, enter on negotiations with one or more hospitals, and induce them to hand their hospital over to them for university purposes. 4. As regards the hospital governors, the problem placed before them by the newly organised senate will be to allow this university faculty to modify their entire existing arrangements in some radical manner to suit university requirements—in short, to control the hospital; while the hospital managers continue, as before, to raise all the money necessary to keep the hospital going. 5 There is a further problem—most clearly presented by Sir William Osler in his evidence before the Commission. He was asked: "Supposing the hospital governors refuse to hand their hospital and its control over in the way suggested, what influence of a compulsory character could you bring to bear upon them?" and the reply was: "I do not know, Sir."

NATIONAL CHARACTERISTICS IN MEDICAL SCIENCE.

National characteristics play an important part in medical science as they do in all other spheres of human activity. They have played an all-important part in the development of English medical education and medical observation. In the case of English medicine, that characteristic has been *individualism*—shown in connexion with the foundation alike of hospitals and schools, and no less manifested by the individual philanthropy which originally created and still underlies and supports the English hospital system. In the case of Germany the national characteristic has, on the contrary, been essentially governmental and bureaucratic, all hospitals and medical faculties being supplied and maintained by combined State and municipal aid. In America there has been exhibited individualism—rampant to a degree quite unknown in the history of any country—condoned, connived at, and even legalised by a degree of recognition and support on the part of individual States and municipalities totally unknown in the history of medicine in this or in any other country.

MEDICAL EDUCATION IN AMERICA.

No greater service has ever been rendered to American medicine than the full, clear, and remarkable exposure recently (1910) given by Mr. Abraham Flexner of the proprietary nature of scores of the medical colleges, "institutes," quasi-universities, "national medical universities," "colleges of physicians and surgeons," &c., which for many years have given their M.D. in a frankly commercial spirit.

[Dr. Hunter here referred to the case of the "National Medical University," which according to Mr. Flexner, had "no equipment of any sort, and a dirty, unused, and almost inaccessible room as its dissecting room; and its 'hospital' consists of a top floor containing two lonely patients,'" yet it enjoyed from students' fees an (estimated) annual income of £4500.]

The evil of medical education in America—namely, individualism and individual "schools" and "colleges" run rampant—has been signally checked, and is in process of being in due course effectively arrested by a still greater individualism originally created by the munificent foresight of one philanthropist, Johns Hopkins, and given effect to by the brilliant imagination and practical genius of a young pathologist, Professor Welch, to whom at the early age of 28 was entrusted the unique task of formulating the conditions and selecting the professors for the first Faculty of Medicine to govern the new "Johns Hopkins Hospital and University" of Baltimore. His first selection was a young Canadian physician professor, educated in the McGill University of Montreal and in London in the best clinical traditions of English medicine, transferred to the University of Pennsylvania in Philadelphia, thence transferred to the Johns Hopkins University in Baltimore, and finally finding his present home in the ancient University of Oxford—Sir William Osler.

I have recently elsewhere, in the opening address of the McGill University, Montreal, in 1910, paid my tribute to the influence of these two great teachers on the science of medical education. "Under their inspiring spirit and guiding hand, supported by their enthusiastic colleagues and pupils, Anglo-Saxon medicine on the American-Canadian continent has shown itself capable of combining in a degree unknown to English medicine the scientific spirit underlying German work and methods with the great clinical practical outlook which throughout its whole history has specially characterised English medicine." That tribute paid three years ago, without any reference to the problem of medical education in London, has an interesting significance at the present time. For it practically embodies the *Leit-Motif*—the note of "Fate and Gloomy Sorrow" which runs through the whole of the evidence of the Royal Commission on the University of London with regard to medical education—the *motif* which has eventually determined their final recommendations. That *motif* is the excellence of English clinical traditions in hospital work; but the extraordinary defectiveness, insufficiency, inadequacy, absence of organised support, whether from Governmental and public services, or by public opinion, or by private generosity, for the provision for laboratory work and research necessary for the promotion of medical education or the advancement of medical knowledge.

What, then, was the antidote which these pioneer workers introduced into medical education in the United States as they found it in the "eighties," where it still exists—to a degree quite unknown in English medicine. It was the following: that Sir William Osler introduced the clinical traditions of clinical teaching—by the system of clerks and dressers in the wards and continuous relations with and observation of patients; while Professor Welch grafted on to that system the all-essential, supporting, educational, and progressive system of great laboratory institutes created on the lines of German methods and example. This was possible in their case, for they had a clean slate to write upon—a free hand both as regarded money for their hospital and school and as regarded the organisation which they saw fit to adopt.

THE ROYAL COMMISSION'S PROPOSALS.

The proposals now submitted in evidence before the Royal Commission on University Medical Education in London and ultimately adopted and recommended by the Commission are shortly—that similar organisation is necessary to create the proper conditions for placing hospital education in London on a university basis.

Inasmuch as the chief basis of the English system is the clinical traditions of hospital education—the system of clerks and dressers and facilities for hospital work and assistance always freely granted by hospital authorities in this country is admitted by all to be immensely superior to the system obtaining in any other country—it might be thought to be perfectly easy and practicable to graft on to this system for university purposes the laboratories, professors, and assistants necessary to supplement and complete the system. I think myself that that is perfectly practicable, and the matter, having now been referred to a strong Departmental Committee of the Board of Education to draft a Bill to carry this into effect, so far as this portion of university education is concerned, I am quite prepared in common with everyone interested in placing university education on a sound basis in London, to afford them every help in my power. The character of the Departmental Committee is, to my mind, a sufficient guarantee that the distinctive national characteristics and honourable traditions of English medicine (which have been far more fruitful in advancing medical knowledge than some of the sweeping generalisations submitted by witnesses before the Commission realise) will have due weight attached to them.

Still more I am satisfied that the widely different conditions of hospital management and support peculiar to this country and quite unknown to Germany and institutions like the Johns Hopkins Hospital and a few American hospitals—to wit, the voluntary public charitable support and government of the hospitals in this country as contrasted with the State, municipal, bureaucratic control of the German, and the endowed support and control of the newer American hospitals and universities, like the Johns Hopkins—will be better known to, and more fully weighed by, that committee than they could possibly be known to, or weighed by, witnesses unacquainted by practical experience with their working.

To pour new wine into old bottles is proverbially a risky business—which it is said no wise man would attempt to do. To pour a German full-bodied wine compounded of full control of the Minister of Education, Exchequer control in connexion with insurance money, municipal control, and autocratic directing control of two or three professors over the whole of a hospital and of all the laboratories connected therewith, would certainly burst the old bottles (quite decent and useful ones) of the entire voluntary system of hospital support and government existing in this country.

The problem is one of the greatest difficulty. So far from subjecting the Commission's Report to criticism, with regard to the individual recommendations, my own opinion is, *after the closest perusal of the whole volumes of evidence* submitted, that a satisfactory solution of the whole problem of University Reform in London, including that of Medical Education, is to be found in connexion with its fundamental recommendations, in my judgment admirable in character. These are:—(1) Government of the University Court; (2) its *Finan* [illegible] compact and [illegible] of an unwo [illegible] ndependent *and, in many cases, opposing interests*); (3) the creation of a small compact Faculty of Medicine, not merely advisory, but made responsible for the Educational arrangements and provisions subject only to the control of the Senate so far as their Regulations affect the finances of the University.

FINANCIAL NEEDS OF MEDICAL EDUCATION.

The needs of a school are determined by the requirements of full-time students, who are engaged in work in the school and hospital all day. Part-time students, who come for shorter periods of time, share in the arrangements thus provided to their own great advantage, and contribute to the support of the school. 1. To place medical education on a sound basis the fees thus earned, plus any educational grants given by the Board of Education, should be entirely available for the education of the students and for payment of lecturers and demonstrators. On the basis of what is being done in German universities and a few of the schools in America, to which so much attention has been drawn as examples of what the standard of university education should be, these ought to constitute about one-third of the total annual cost of a student's medical education. 2. But this alone is quite inadequate. In addition there is required money for the provision, equipment, and support of the laboratories required for instruction and for payment of the salaries of the professors in charge of the various departments. The amount required for this is about the same as that earned in fees. 3. And, lastly, over and above these requirements there should be a third quotient connected with medical education, available for the promotion of research in the various departments.

ANNUAL EXPENDITURE PER STUDENT.

I estimate, on the basis of *practical* experience, *that the* current annual expenditure for university medical education in London should work out to at least £70 to £80 a year per degree student, or *approximately £80,000 to £100,000* a year. No provision approaching this is available in any of the medical schools of London. It means that two-thirds of the cost of education *must come from sources other* than fees. Owing to the absence of any adequate support from the State, university, or municipal or any public sources, no such funds are available.

The requirements here stated may seem to be large and costly even for a rich country like England. Nevertheless, *they fall below the actual expenditure on medical education* in the universities of Germany. According to official figures supplied by the German Government, the actual expenditure in *10 universities in Germany* amounts to no less than £95 per student, and a total sum of over £500,000 per annum.

COMPARISON BETWEEN A GERMAN AND A LONDON SCHOOL.

[Dr. Hunter then compared the expenditure at the University of Königsberg (370 medical students) with one of the largest London schools (353 full-time and 170 part-time students). The German expenditure was £34,000, or £92 per student annually; the English £14,000, or £40 per student. The State in Gerr [illegible] £63 per student; the Board of [illegible] or £13 per student. Further, [illegible] tributed £29; there was no university contribution in England. The departmental expenditure in the German university was £24,500, of which £14,000 were for clinical salaries, teaching, and work; in the English school £6000, of which only £1500 were available for clinical teaching.]

There is not much comforting in this contrast either to the English Government or English public opinion. In my opinion the financial conditions of medical education in this country are a discredit to all parties concerned, except only the medical schools and their devoted band of teachers who support the whole cause of medical education in London on behalf of 70 per cent. of the total students of England, under greatest difficulties, without financial support, without recognition, and without even sympathy.

If I might venture to make any criticism on the Final Report of the Royal Commission it would be that this financial aspect of medical education in London has not been brought out in connexion with the comparisons of a startling and invidious character between English medical education and German medical education to which so much weight has been attached. The prosperity of university medical education in London would be enormously promoted by providing three to nine professors in certain selected schools of London, each of them with £4000 *at its disposal for* the development of medical and surgical science and teaching in the University, as proposed by the Royal Commission. The total sum of £36,000 a year thus *provided for salaries and working expenses* would not, however, solve the problem which it is sought to solve—salaries to full-time professors and their assistants, and the providing and maintaining and paying adequate scientific and final laboratories connected with the schools selected. It is little more than that referred to in the expenditure on one moderate-sized German university. And this is apart from any capital outlay necessary for the provision of new laboratories.

[Dr. Hunter *next compared the annual current expenses* of 10 medical schools in London with 1122 full-time and 765 part-time students, with those of the Medical Faculty *of the University of Berlin with Charité Hospital (2000* students), and the respective State grants in each case, showing the grant to be about £12 per full-time student in *London as against £49 in Berlin.*]

THE BOARD OF EDUCATION AND THE MEDICAL SCHOOLS.

Small as this grant is *relatively, it has been of the most* material help to every school which has been in receipt of it. In the case of the Charing Cross School, as I can testify [illegible] *it has made all the difference in* [illegible] which [illegible] to the *University, to King's College, and to the school.* The increase of efficiency, equipment, laboratory accommodation, facilities for teaching and research which it has helped to *bring about for the benefit of 250 students of the school and* the University laboratories who have had the advantage of them during the past year has been very great. Apart from *the amount of the grant* itself, and the increased efficiency thereby produced, it has given the school great encouragement to know that for the first time in their history a great public department of the State is interested in their work for medical education and the provision made for carrying it out effectively.

It is *only some* four or five years since the Board first began to make their grants. The information which they have yearly before them, and which they so carefully analyse and report, has been of the greatest service to the cause of medical education and its university reform—the facts brought out have given the greatest stimulus to better efficiency which the medical schools in their history have ever received.

Here, then, the picture of English medical education as it is drawn by a distinguished American educationist (not a doctor) is sharply outlined. If the shadows are too deep in places and wrongly placed his object is the highly laudable one, beneficial to education, of directing attention to the existence of the picture at all—not necessarily to its completeness or absolute technical accuracy.

The problems facing University medical education in London, as here presented, are thus the following formidable ones: 1. To create, in the first place, a university which will be concerned and *financially able* to give any education at all to its students in their final hospital and school studies. For this the University of London has, so far, never done. 2. To create a *new Senate*, limited in number to 10 or 15 men, with the fullest financial, administrative, and executive control over the whole affairs of the University. 3. To create a new *Faculty of Medicine*—small, compact, and sufficiently business-like in its methods to be able to draw up a scheme, enter on negotiations with one or more hospitals, and induce them to hand their hospital over to them for university purposes. 4. As regards the hospital governors, the problem placed before them by the newly organised senate will be to allow this university faculty to modify their entire existing arrangements in some radical manner to suit university requirements—in short, to control the hospital; while the hospital managers continue, as before, to raise all the money necessary to keep the hospital going. 5 There is a further problem—most clearly presented by Sir William Osler in his evidence before the Commission. He was asked: "Supposing the hospital governors refuse to hand their hospital and its control over in the way suggested, what influence of a compulsory character could you bring to bear upon them?" and the reply was: "I do not know, Sir."

NATIONAL CHARACTERISTICS IN MEDICAL SCIENCE.

National characteristics play an important part in medical science as they do in all other spheres of human activity. They have played an all-important part in the development of English medical education and medical observation. In the case of English medicine, that characteristic has been *individualism*—shown in connexion with the foundation alike of hospitals and schools, and no less manifested by the individual philanthropy which originally created and still underlies and supports the English hospital system. In the case of Germany the national characteristic has, on the contrary, been essentially governmental and bureaucratic, all hospitals and medical faculties being supplied and maintained by combined State and municipal aid. In America there has been exhibited individualism—rampant to a degree quite unknown in the history of any country—condoned, connived at, and even legalised by a degree of recognition and support on the part of individual States and municipalities totally unknown in the history of medicine in this or in any other country.

MEDICAL EDUCATION IN AMERICA.

No greater service has ever been rendered to American medicine than the full, clear, and remarkable exposure recently (1910) given by Mr. Abraham Flexner of the proprietary nature of scores of the medical colleges, "institutes," quasi-universities, "national medical universities," "colleges of physicians and surgeons," &c., which for many years have given their M.D. in a frankly commercial spirit.

[Dr. Hunter here referred to the case of the "National Medical University," which according to Mr. Flexner, had "no equipment of any sort, and a dirty, unused, and almost inaccessible room as its dissecting room; and its 'hospital' consists of a top floor containing two lonely patients,'" yet it enjoyed from students' fees an (estimated) annual income of £4500.]

The evil of medical education in America—namely, individualism and individual "schools" and "colleges" run rampant—has been signally checked, and is in process of being in due course effectively arrested by a still greater individualism originally created by the munificent foresight of one philanthropist, Johns Hopkins, and given effect to by the brilliant imagination and practical genius of a young pathologist, Professor Welch, to whom at the early age of 28 was entrusted the unique task of formulating the conditions and selecting the professors for the first Faculty of Medicine to govern the new "Johns Hopkins Hospital and University" of Baltimore. His first selection was a young Canadian physician professor, educated in the McGill University of Montreal and in London in the best clinical traditions of English medicine, transferred to the University of Pennsylvania in Philadelphia, thence transferred to the Johns Hopkins University in Baltimore, and finally finding his present home in the ancient University of Oxford—Sir William Osler.

I have recently elsewhere, in the opening address of the McGill University, Montreal, in 1910, paid my tribute to the influence of these two great teachers on the science of medical education. "Under their inspiring spirit and guiding hand, supported by their enthusiastic colleagues and pupils, Anglo-Saxon medicine on the American-Canadian continent has shown itself capable of combining in a degree unknown to English medicine the scientific spirit underlying German work and methods with the great clinical practical outlook which throughout its whole history has specially characterised English medicine." That tribute paid three years ago, without any reference to the problem of medical education in London, has an interesting significance at the present time. For it practically embodies the *Leit-Motif*—the note of "Fate and Gloomy Sorrow" which runs through the whole of the evidence of the Royal Commission on the University of London with regard to medical education—the *motif* which has eventually determined their final recommendations. That *motif* is the excellence of English clinical traditions in hospital work; but the extraordinary defectiveness, insufficiency, inadequacy, absence of organised support, whether from Governmental and public services, or by public opinion, or by private generosity, for the provision for laboratory work and research necessary for the promotion of medical education or the advancement of medical knowledge.

What, then, was the antidote which these pioneer workers introduced into medical education in the United States as they found it in the "eighties," where it still exists—to a degree quite unknown in English medicine. It was the following: that Sir William Osler introduced the clinical traditions of clinical teaching—by the system of clerks and dressers in the wards and continuous relations with and observation of patients; while Professor Welch grafted on to that system the all-essential, supporting, educational, and progressive system of great laboratory institutes created on the lines of German methods and example. This was possible in their case, for they had a clean slate to write upon—a free hand both as regarded money for their hospital and school and as regarded the organisation which they saw fit to adopt.

THE ROYAL COMMISSION'S PROPOSALS.

The proposals now submitted in evidence before the Royal Commission on University Medical Education in London and ultimately adopted and recommended by the Commission are shortly—that similar organisation is necessary to create the proper conditions for placing hospital education in London on a university basis.

Inasmuch as the chief basis of the English system is the clinical traditions of hospital education—the system of clerks and dressers and facilities for hospital work and assistance always freely granted by hospital authorities in this country is admitted by all to be immensely superior to the system obtaining in any other country—it might be thought to be perfectly easy and practicable to graft on to this system for university purposes the laboratories, professors, and assistants necessary to supplement and complete the system. I think myself that that is perfectly practicable, and the matter, having now been referred to a strong Departmental Committee of the Board of Education to draft a Bill to carry this into effect, so far as this portion of university education is concerned, I am quite prepared in common with everyone interested in placing university education on a sound basis in London, to afford them every help in my power. The character of the Departmental Committee is, to my mind, a sufficient guarantee that the distinctive national characteristics and honourable traditions of English medicine (which have been far more fruitful in advancing medical knowledge than some of the sweeping generalisations submitted by witnesses before the Commission realise) will have due weight attached to them.

Still more I am satisfied that the widely different conditions of hospital management and support peculiar to this [illegible] bers, For [illegible] the dis- [illegible] It is not unlikely that the [illegible] field may receive a practic [illegible] this subject we may help to [illegible] immense sanitary gain in the field, and thereby a most valuable asset to the nation. At the risk of wearying you I should like to make further calls upon our members with a view to producing papers upon other subjects which may bear upon the health of the sailor or the soldier, and would ask those who have studied any problem likely to be of benefit to the Services not to hesitate to bring such before us. I feel sure that they will be welcomed heartily and that discussion will help the authors, while it widens the scope of thought of every individual.

And here I would ask members who may be diffident because they are junior in rank not to permit such false modesty to restrain them from joining in our discussions, and if they have no superlative opinion of their own intelligence, I would remind them that this society is not official. They will lose nothing by making their thoughts known. The words of thinking men of all ages are worth due consideration, and therefore I hope that all who have studied any medical problem, besides those I have touched upon, will express freely any opinions or experiences they feel would give completeness to our discussions. They will add thereby to the value of our deliberations, and extend our scope of usefulness.

HARD v. SOFT WATER.

By JOHN C. THRESH, M.D. VICT., D.Sc. LOND.,
MEDICAL OFFICER OF HEALTH OF THE COUNTY OF ESSEX.

IN the annual report for the county of Essex for the year 1910 I gave a series of statistics showing that (1) in the areas supplied with hard water the death-rate is quite as low as, if not actually lower than, that in the areas supplied with a soft or moderately hard water; and that (2) filtered river water, even when the river water impounded is known to be more or less sewage-polluted, is as wholesome as the water from the deep wells and springs in this county. These conclusions were based upon the statistics for one year only. The report proved of such interest that more copies were applied for than I could supply, and the applications were not limited to this country, the subject being one of equal importance in all parts of the world. When the Census returns for 1911 were received and the Registrar-General supplied me with factors for the correction of the death-rates on account of differences in age and sex distribution of the population in every district of the county, I decided to again consider the subject and take a period of five years as the basis for comparison. The results now given, therefore, are much more reliable than those published in 1911, but they support entirely the conclusion at which I then arrived.

The areas taken are exactly the same as before with the exception that in Group IV I have included the Romford rural district. The reason for this is that it is decidedly urban in character and the great bulk of the population is supplied with the same water as that used in the Romford urban district.

Besides giving the average death-rates for the five years 1907–11 (inclusive) I have also given the death-rates for 1912, all corrected.

GROUP I.
(Hardness of water supply under 10° per 100,000.)
Soft Water Area.

	Averages for years 1907–11.		Year 1912.	
	Population.	Death-rate per 1000.	Population.	Death-rate per 1000.
Burnham	3,150	8·9	3,200	11·5
Leigh-on-Sea ...	7,100	10·1	8,550	10·7
Maldon	6,100	11·0	6,335	11·5
Shoeburyness ...	4,800	10·3	5,075	8·7
Southend-on-Sea	56,200	11·2	67,280	9·7
Totals and averages	77,350	11·0	90,440	10·0

[illegible]

(Hardness of water supply between 10° and 20°.)
Moderately Hard Water Area.

	Averages for years 1907–11.		Year 1912.	
	Population.	Death-rate per 1000.	Population.	Death-rate per 1000.
Braintree	6,100	12·8	6,170	13·3
Brightlingsea ...	4,500	10·7	4,390	12·1
Colchester	41,890	12·1	44,160	10·7
Saffron Walden ...	6,230	9·7	6,350	7·6
Witham	3,470	10·3	3,420	14·0
Wivenhoe	2,400	7·9	2,500	10·4
Totals and averages	64,090	11·5	67,030	10·9

These country towns all derive water from sources similar to Group I., but the Colchester deep well supply is supplemented by water from gravel springs.

GROUP III.
(Hardness of water supply 20° to 30°.)
Hard Water Area.

	Averages for years 1907–11.		Year 1912.	
	Population.	Death-rate per 1000.	Population.	Death-rate per 1000.
Clacton	9,300	12·0	9,830	9·2
Chelmsford ...	17,000	9·2	18,300	8·9
Epping	4,150	9·1	4,300	7·1
Frinton	1,400	8·0	1,570	8·5
Walton	2,150	9·9	2,190	9·9
Harwich	13,200	14·1	13,970	12·9
Halstead	6,200	12·0	6,300	9·0
Totals and averages	53,400	11·2	56,430	9·9

The Clacton supply is from springs, as is also a small proportion of the Chelmsford supply. The remainder derive *water from deep wells in the chalk.*

GROUP IV.
South Essex Area.—Moderately Hard Water.

	Averages for years 1907–11.		Year 1912.	
	Population.	Death-rate per 1000.	Population.	Death-rate per 1000.
Barking	30,770	13·0	32,520	10·6
Brentwood ...	6,600	8·8	6,940	6·2
Grays	15,810	11·0	16,420	10·7
Romford	16,550	10·2	17,600	9·5
Romford Rural ...	23,860	10·5	26,000	9·3
Totals and averages	93,490	11·2	99,480	9·9

These localities are all supplied with chalk water by the South Essex Water Company.

GROUP V.
Metropolitan Water Board Area.—Hard Water.

	Averages for years 1907–11.		Year 1912.	
	Population.	Death-rate per 1000.	Population.	Death-rate per 1000.
Buckhurst Hill	4,800	10·2	4,900	9·1
Chingford	6,500	8·55	8,000	8·9
East Ham	126,600	12·1	133,450	11·1
Leyton	122,100	10·4	123,700	10·8
Loughton	5,300	9·7	5,500	10·8
Waltham Cross .	6,650	11·35	6,830	10·0
Walthamstow .	118,500	11·6	123,480	10·4
Wanstead .. .	13,200	8·5	15,700	7·2
Woodford	17,050	9·3	19,070	9·4
Totals and averages	421,300	11·1	454,310	10·6

Summarising the tables we obtain the results as under:—

	Death-rate per 1000, 1907–11			Death-rate per 1000, 1912.		
	Average	Extremes.		Average.	Extremes.	
		Maximum.	Minimum.		Maximum.	Minimum.
Soft water area	11·0	11·2	8·9	10·0	11·5	8·7
Moderately hard water areas—						
(a) Country towns	11·5	12·8	7·9	10·9	14·0	7·6
(b) South Essex area	11·2	13·0	8·8	9·9	10·7	6·2
[illegible]	11·2	14·1	8·0	9·9	12·9	7·1
[illegible]	11·1	12·1	8·6	10·6	11·1	7·2

Arranged in order of death-rates we obtain the following interesting results :—

Average for 1907-11.

Soft water area	11·0	per 1000.
Hard water area (metropolitan)	11·1	"
" " " (country towns)	11·2	"
Moderately hard water area (South Essex) ...	11·2	"
" " " " (country towns)...	11·5	"

Average for 1912.

Hard water area (country towns)	9 9	per 1000.
Moderately hard water area (South Essex) ...	9 9	"
Soft water area	10 0	"
Hard water area (metropolitan)	10 6	"
Moderately hard water area (country towns)...	10 9	"

Naturally there are greater variations in the rates for single years than in the rates for a series of years, but it is obvious that there is no co-relation in either tables between the hardness of the water and the death-rates.

Taking the average for the five years the difference between the death-rate for the area with the softest waters and the area for hardest waters is, in one instance (the metropolitan area), only 0·1 per 1000, and in the other (country towns) only 0·2 per 1000, whilst the moderately hard water areas taken together have a death-rate exceeding that of the hard water areas of from 0 1 to 0·2 per 1000. These differences are so slight that only one conclusion can be deduced—namely, that the character of water-supplies in this county has no effect upon the death-rates.

Incidentally they also confirm the opinion expressed in my previous report that the filtered water from the sewage-polluted rivers, the Thames and the Lea, is as wholesome as the water from our very deep wells and gravel springs. As comparatively little water is taken from springs we may say that the filtered river water is as wholesome as the water from our deep wells, which are celebrated for their great organic purity.

In the report for 1910 I also showed that the incidence of cancer, phthisis, and enteric fever bore no relation to the water-supplies. The statistics for the five years are as under :—

Death-rates from Various Diseases in the Respective Water Areas for the Five Years 1907–11.

	Cancer.	Phthisis.	Enteric fever.
Soft water area	1·0	0 99	0 043
Moderately hard water areas—			
(*a*) Country towns	0·84	0 81	0 021
(*b*) South Essex area	0·86	0 90	0·121
Hard water areas—			
(*a*) Country towns	0·81	0 75	0 04
(*b*) Metropolitan area	0 83	0 81	0·041

The excessive mortality from cancer and phthisis in the soft water area is entirely due to that area including a large and populous seaside resort, and the medical officer of health has shown that fully 25 per cent. of the people who die there from these diseases were actually suffering therefrom when they entered into residence. In fact, they came to reside there in the hope of becoming cured or of prolonging life. When this excess is allowed for there is no excessive incidence in the soft water area.

The tabulated results afford no indication whatever of the hardness or softness of the water having any bearing upon the prevalence of or mortality from any of the three above-mentioned diseases.

It is important to note, however, in connexion with this investigation that the soft waters of Essex differ materially from the soft moorland and upland waters so widely used for the purposes of public supply. These waters contain very little saline matter and often contain so much free carbonic acid as to render them "acid" in character. The soft Essex waters contain no free carbonic acid, and all contain marked quantities of sodium bicarbonate, and may therefore be said to be "alkaline" in character. The inquiry therefore shows that such alkaline waters are perfectly wholesome, as wholesome, in fact, as waters from any other source.

ARTERIO-VENOUS ANASTOMOSIS FOR IMPENDING GANGRENE;

A REPORT OF 15 CONSECUTIVE CASES WITH ARTERIO-VENOUS ANASTOMOSIS OF THE FEMORAL VESSELS.

BY DR. CHARLES GOODMAN.

THE employment of arterio-venous anastomosis as a clinical procedure has given such widely different results in the hands of different operators, and has led to such a divergence of opinion on the part of these various operators as to the possibility of establishing a reversal of the circulation, that we have attempted the procedure in 15 cases in order to throw some light on the subject; we believe this to be the largest number of cases yet reported from a single source.

In a review of the literature by Halstead and Vaughan, published in January, 1912, they recall that Frank in 1881 was the first man to attempt an arterio-venous anastomosis. Since then many attempts have been made to produce a satisfactory arterio-venous anastomosis in animals, but without success, until in 1902 Carrel reported his perfected technique, and later in 1905 his work with Guthrie. It is the work of Carrel more than that of any other man that has led the surgeon to employ this procedure on the human being. Stich, Touffier, Frouin and Watts, Cottard and Leriche, and others have since then reported successful anastomoses in animals.

The first attempt to perform arterio-venous anastomosis in man was made by San Martin y Satrustegui in 1902, which proved unsuccessful. In 1912 Bernheim, of Johns Hopkins Hospital, reported 6 operations with 4 successes, and in his review of the literature reports and tabulates 52 operations which were performed by 32 operators; of these, only 15 were successful. End-to-end suture according to the method of Carrel was employed 23 times with 8 successes; lateral 12 times with 4 successes; invagination, end of artery into end of vein, twice with 1 success; intubation according to the method of Wieting, 9 times with 2 successes. Bernheim ascribes the large number of failures, first to the large number of operators; secondly, to the fact that a number of the cases were seen late in the course of the disease; and thirdly, that vascular surgery is still in its infancy and offers many technical difficulties.

The possibility of establishing a reversal of the circulation in an extremity has been questioned by Coenen and Wiewerowski, who have presented an array of experimental work against the practicability of the procedure. These views, however, as to the impossibility of the procedure on physiological grounds have been controverted by 15 successful cases.

As to indications, arterio-venous anastomosis is applicable in angeiosclerosis and in arterial thrombus, where the integrity of the limb may be preserved by this means until collateral circulation is established. In regard to methods, end-to-end anastomosis offers the most simple technique and is least likely to be followed by thrombosis.

We have tried the operation in 15 cases, and in this series we noted that the foot, previously cold and cadaverous in appearance, took on a feeling of warmth and a healthy pink colour. The valves of the veins were only a temporary barrier to the course of the blood against the constant pounding of the heart. The pain due to ischæmia was relieved shortly after the operation in all these cases. Strongly presumptive evidence of establishing a reversal of the circulation are the following facts: improvement of colour, increase of warmth of the affected part, relief from pain, filling of the superficial veins, pulsation of veins below site of anastomosis, and return of part threatened with gangrene, or the actual seat of gangrene, to the normal. All writers seem to agree that angeiosclerosis of the lower extremity is an ascending process and leads eventually to gangrene.

A review of our cases shows 6 successes. Several of these cases which promised success required amputation later, but even these had temporary relief from pain. In our experiments upon animals we have tried all the usual methods of anastomosis—end-to-end, side-to-side, end-to-side, intubation, and invagination. In our operations upon human beings we have used the end-to-end method in all excepting one case, as we found it the simplest in execution and least likely to cause thrombosis. The operation should not be undertaken in the presence of sepsis, advanced or fulminating gangrene. The opportune time for intervention is in the pre-gangrenous stage before mortification has set in, in order to prevent its inception. In non-septic gangrene the improved nutrition of the limb may be hoped for, permitting lower amputation than would otherwise be possible, as is shown in several of our cases.

The utmost delicacy and skill in minute detail must be observed in order to avoid the formation of thrombi; a most rigid asepsis is required throughout the operation, or the object of the operation will be defeated. To reduce the dangers of thrombosis to a minimum we have practised the following *precautions. Before the sheath of the vessel is* opened the wound must be absolutely freed from, and dried of, any visible signs of blood, and then covered with sterile wound protectors. For this purpose we have used various materials and have found that a thin, black, oriental silk is best suited to this purpose; this material adapts itself to the wound without encroaching upon the operative field, and the colour removes the glaring and trying effect of the open wound upon the eyes of the operator during the more minute details of the operation.

The etiology of the condition which requires this operation *is still obscure. With a view of throwing some light on the* subject we have enlisted the coöperation of the laboratories of the hospital, and hope in the future to be able to advance some information regarding the disease. We can only hope that the operation will relieve the symptoms, arrest impending gangrene, and save the limb

As an instance I will cite briefly the first one of our cases.

The patient, a man aged 35, referred to me by Dr. I. Seff, was admitted to Beth Israel Hospital on July 17th, 1912, with endarteritis of the left leg, nec[illegible] the shin. He ha[illegible] for which an amp[illegible] swollen and the [illegible] an ulcer appeare[illegible] refused to heal.

When the patient was re[illegible] with great difficulty. The [illegible] natural size, was dusky i[illegible] necrotic, being extremely p[illegible] of the limb was followed [illegible] limb was suspended it bec[illegible] the size of half a dollar occ[illegible] shin. Pulsation could not be felt below Scarpa's triangle, [illegible]

Arterio-venous anastomosis of the femoral vessels was performed on [illegible] d the [illegible] to be [illegible] rses, [illegible] laced [illegible] a con [illegible] was [illegible] iched appearance changed to a pink colour and his pain was immediately relieved. On July 24th (the third day) the patient said, "I am more comfortable than I have been for a year." On the fourth day the dressings were opened to inspect the limb, and very much to our [illegible] limb became m[illegible] wound, which [illegible] evidences of [illegible] followed by a [illegible] pressure on the vessels, for after it was evacuated the œdema disappeared and the toe began to heal. (This fluid was undoubtedly due to an excessive amount of vaseline which I had used during the opera-[illegible] e was entirely [illegible] iscomfort and [illegible]

The ages of our cases varied from 28 to 87 years. There were 13 end-to-end anastomoses, 1 side-to-side, and in 2 of the cases an exposure of the vessel showed that an attempt to anastomose was not warranted on account of the advanced stage of thrombosis of the vessels. In 2 of our cases with gangrene a low amputation seemed to be satisfactory. Of the 8 cases which were failures, including 1 death, 1 was a side-to-side anastomosis, and 3 of the remainder should not have been operated upon on account of the presence of *spreading gangrene.*

The predisposing factors in the causation of the symptom-complex of the disease and the results so far obtained by operation warrant us in believing that, whenever the operation is undertaken before gangrene has actually set in, the distressing symptoms can be relieved without the sacrifice of the limb to amputation, which heretofore has afforded the only means of relief.

In conclusion, I should like to emphasise that in the absence of infection, even if the lines of the vessels are not evenly approximated, the chink will be filled in with blood clot. As long as this minute blood clot does not project into the lumen of the vessel there is no accretion and it does no harm. Fibrous connective tissue will grow in and organise the blood clot, and the cells which finally reach the surface will *become competent as endothelial cells.* In other words, a foreign body in blood-vessels, such as a suture, if it is contaminated with ferment, will produce thrombosis. This is exactly what has been attempted in the treatment of aneurysm with electrolysis; the current kills a certain number of blood cells, a certain quantity of ferment is liberated, and accordingly a certain degree of thrombosis is produced. The secret therefore, of suturing blood-vessels and retaining the normal continuity of the vessels is to render the operative field as free as possible from thrombo-kinase.

New York.

FORMATION OF AN ARTIFICIAL VAGINA BY TRANSPLANTATION OF A PORTION OF THE ILEUM (BALDWIN'S OPERATION);

WITH REMARKS ON THE ETHICAL ASPECT OF THE PROCEDURE.

BY VICTOR BONNEY, M.S., M.D., B.SC. LOND.,
F.R.C.S. ENG., M.R.C.P. LOND.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN; ASSISTANT GYNÆCOLOGICAL AND OBSTETRIC SURGEON TO THE MIDDLESEX HOSPITAL; GYNÆCOLOGICAL SURGEON TO THE MILLER GENERAL HOSPITAL, GREENWICH-ROAD, S.E., ETC.

THE surgical treatment of congenital absence of the vagina was extremely unsatisfactory until the American surgeon Baldwin introduced the operation associated with his name, whereby a piece of the ileum transplanted between the bladder and rectum is made to do duty for the missing canal. The method surmounts the chief difficulty that beset all former procedures—namely, the extreme liability for the artificial vagina to contract and prove useless for coitional purposes.

The ethical aspect of the operation provides a wide field for individual opinion, for though its result achieves fitness for the *sexual act, sterility must remain in spite of it in the* vast majority of cases. Before, however, embarking on this subject I will relate the details of the following case:—

History.—The patient, a girl aged 19 years, was brought to me in 1912. She was stout, well grown, and good looking, and externally all the feminine characteristics were well developed, but she had never *menstruated.* On account of the amenorrhœa her mother took her to a practitioner, who found complete absence of the vagina. She was sent into a hospital under a gynæcological surgeon, who dis-[illegible] umbilicus. On exploring I found both ovaries unusually well developed, one of them containing a large recently dehisced follicle. The upper ends of both Mullerian ducts were well formed, a mesosalpinx and the ampullary segment of the tube with the fimbri [illegible] present on either side, but below this they [illegible] solid cords which after joining with the round [illegible] in the middle line to form a little nodule of [illegible] the bladder. The terminal portion of the ileum was pulled up and a loop of it chosen about eight inches long where the mesentery was found to be longest; the centre of this loop was about ten inches distant from the ileo-cæcal valve. This loop was then isolated by dividing the bowel at either end of it, closing those ends by suture and restoring the continuity of the intestine by an end-to end anastomosis The mesentery was then divided nearly down to its base in a V shaped manner, so that the isolated segment of ileum merely remained attached by a narrow pedicle The edges of the mesentery in the continuity of the bowel were brought together by sutures An assistant now pushed upwards the forceps previously placed in the site of the future vagina, and the little nodule representing the union of the Mullerian ducts and the rest of the tissue over the forceps was divided until they could be pushed into the peritoneal cavity. The isolated loop of ileum was now seized at its middle and pulled downwards into the vaginal site until the part held by the forceps appeared at the vulva. This was the difficult part of the operation. The patient was very fat, of the stout "cobby" build, and the mesentery was short Moreover, I had isolated an unnecessarily long segment of the gut. It was not until I had shortened this considerably and further divided the mesentery holding it that I was able to get it entirely into position. The peritoneum between the bladder and rectum was now stitched over it and around its mesentery, and the abdominal wound was closed in the usual way. The patient was now placed in the lithotomy position again, and the loop of gut opened at its apex attached by interrupted sutures to the edges of the vulval wound, and lightly packed with gauze

Result.—The patient made a good recover [illegible] survived and adhered. For some weeks the [illegible] vaginal dilators was practised, but when it [illegible] contracture was going to occur this was desisted from.

The local condition now is that of a septate vagina, each limb of which easily admits the finger. I had intended dividing this septum to make a single canal as practised by Baldwin, but when I last saw the patient it had retracted considerably to form a spur, and I therefore decided to leave it alone. If she marries and the spur gives rise to difficulty, it can easily be divided. The canal appears at present to be sufficient for coitus; it is quite free from pain or tenderness. Since the operation the patient has had a watery mucous discharge, yellow in colour and flocculent in appearance, but this is much less than it used to be The depression has disappeared and she is bright and cheerful.

Those interested in the surgery of congenital absence of the vagina should read Balfour Marshall's admirable review of the subject in the twenty third volume of the *Journal of Obstetrics and Gynæcology of the British Empire.* He there points out that 15 cases of ileum transplantation have been performed, 11 by Baldwin's method and 4 by that of Mori, which only differs from that of Baldwin in that he uses a single instead of a doubled up loop of the intestine All the cases recovered. That a very definite risk attends the operation is, however, not to be denied.

The Ethical Aspect of the Operation.

Turning now to the ethical aspect of the operation certain authorities hold that where childbearing is impossible the procedure, merely to enable coitus to take place, is unjustifiable. I cannot agree with this view, which assumes that the whole object and usefulness of marriage lies in child-bearing. From the racial aspect it is no doubt true, but there are other points of view, the social and the personal, which much more directly influence the individual. That married life may be happy and useful though the wife is obligatorily sterile is common experience. Many women have married after hysterectomy, or even double oöphorectomy and yet enjoyed connubial felicity. To a certain proportion of men the fact that their wife cannot have children is no drawback, and though marriage when sterile is a failure as far as regards the race, yet if it brings happiness to the parties concerned it has a very definite social and individual value To condemn the unfortunate sufferer from this deformity to abandon for ever the natural hope of some day meeting with a companion and support in the battle of life therefore seems to me to be wrong.

On the other hand, it is important to bear in mind that in a certain proportion of these patients the ovaries are undeveloped and the sex sense wanting. Intercourse in the absence of sexual feeling on the part of the woman is very apt to be unsatisfactory even with a normal condition of the parts. Much of the domestic unhappiness that the practitioner sees has it origin in this cause.

In children.—The construction of an artificial vagina should never, therefore, be undertaken until after puberty, for not till then can the fitness of the woman for marrying be estimated or her wishes on the subject consulted.

In unmarried women.—In the larger number of cases of congenital absence of the vagina the girl is brought to the medical man merely because the menses have failed to appear and not because she is suffering either physically or mentally or because marriage is in contemplation. Examination reveals absence of the vagina, a rudimentary condition or complete absence of the uterus, and not infrequently undeveloped ovaries. In my experience these patients are usually conspicuously healthy. Under circumstances such as these no operation is indicated, and, indeed, it will be found that neither the patient nor her parents have any wish for it directly they are satisfied that the absence of the monthly periods is not detrimental to health. The state of affairs ought, however, to be made clear to the mother if possible, and the feasibility of partly overcoming the results of the deformity should marriage be contemplated should be explained to her. For future guidance inquiry should be made as to whether monthly sensations indicative of a "period" (and therefore of functional activity of the ovaries) are noticed by the patient.

There is another class of case, however, in which an unmarried girl is brought to the practitioner, either because (1) the deformity is giving rise to physical suffering owing to retention of menstrual blood in the uterus; (2) marriage is in contemplation; or (3) the knowledge of the deformity is producing mental symptoms.

1. Cases of hæmatometra due to absence of the vagina are very rare, because in most instances the deformity is associated with a non-development or a complete absence of the uterus. There can be no doubt that it would be possible to combine Baldwin's operation with implantation of the uterus into the transplanted segment of ileum, but the procedure has never yet been carried out. An alternative would be to perform Pfannenstiel's operation, in which, after loosening the uterus, the organ is [illegible] rectum and bladder and the cerv [illegible] mucous membrane. Unfortunately, most of these cases present themselves late and after the retained blood has led to hæmatosalpinx and pelvic peritonitis. Under these conditions an attempt to conserve the uterus would be a mistaken policy, and it would be better to remove it.

2. Where marriage is in contemplation the question of the propriety of the operation requires careful consideration. The character of the patient, the degree to which she desires marriage, her fitness for that state as evidenced by a history of menstrual molimina and the possession of normal sex feelings, should all be inquired into, and the nature of the operation and its limitations and risk must be explained to her. The wishes of the parents must also be consulted, whilst as regards the fiancé it would be best for the medical man himself to explain to him the state of affairs. Where a consensus of opinion in favour of the operation is arrived at by the interested parties the operation is, I think, entirely justifiable.

3 Where the knowledge of the deformity is producing mental symptoms, as in the case I have just recorded, and where after full explanation both the girl and her parents are agreed in desiring the operation, it is, in my opinion, right to perform it

In married women—Finally, we come to that class of patient in whom marriage has occurred before the deformity has been recognised, when remedial measures may be sought for: (1) as a sheer act of self-sacrifice on the woman's part, she herself having no sexual desire; or (2) to satisfy the sex sense of both parties.

1 It has been pointed out that a proportion of these patients are sexually deficient, and that under such circumstances the mere provision of a coitional vagina is not likely to be satisfactory from the marital standpoint. Where the patient asks for the operation solely under pressure of her husband's desires, I am of opinion that both he and the surgeon who performs it incur very grave responsibility. Sad cases of this type are sometimes met with Some years ago a patient was sent to me with the following history. She married without knowing her disability. In spite of it, however, her husband was faithful and they lived together happily. They adopted a little girl as they could

have no children of their own. When this girl grew up illicit relations became established between her and the husband, who deserted his wife to go and live with her adopted daughter. The unfortunate woman believed that rectification of her deformity would be the means of bringing her husband back to her. I, of course, refused to operate. No man whose affection was real and worth keeping would entertain the idea of his wife risking her life solely for his gratification. In the case of such individuals the divorce court provides the proper solution of the difficulty.

2. Where, however, the sex sense of the woman is active, and she desires the operation not merely to satisfy her husband but for her own gratification as well, the case is different, and if after the nature, limitations, and risks of the procedure have been explained to the parties the patient elects to undergo it the surgeon is, I think, entirely justified in performing it.

Devonshire place, W.

THE USE OF ATROPINE TABLETS FOR THE DETERMINATION OF REFRACTION IN CHILDREN.

BY FRANK MOXON, M.B., B.S. DURH.,
CHIEF CLINICAL ASSISTANT AT THE ROYAL LONDON OPHTHALMIC HOSPITAL.

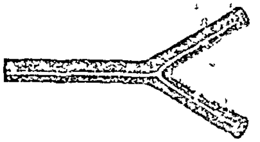
SINCE first undertaking the treatment of London County Council school children in the special department set apart for these cases at the Royal London Ophthalmic Hospital (Moorfields) in 1910, I have for varying periods made use of tablets of atropine for refraction, and have done so continuously since September, 1912. Ever since then I have been increasingly convinced both of the convenience and of the efficacy of this means of effecting paralysis of accommodation in children. In this short paper it is my wish to give a brief account of my experience with this method in the hope that more will be led to give it a trial.

In most hospitals and school clinics atropine is still ordered for children in refraction cases, either in the form of an ointment or of solution containing from 0 5 per cent to 1 per cent of atropine. The directions given for its use in these forms show a diverse and uncertain opinion as to the *time necessary to obtain paralysis of accommodation*; in the majority of cases ointment or drops are ordered to be used twice, three, or even four times a day, for anything from two, more often from four to seven, or even 14 days before the refraction is estimated. I contend that this practice is quite unnecessary, and a not inconsiderable waste of both time and expense, not only to the parents or guardians, but also to the hospital

In justification of this custom of giving atropine one is told that it is the most convenient method, and that it is a saving of time. It may be so if the one who orders the ointment or drops does not also do the refraction on the return of the child, but in no other circumstances; and in any case I consider that the fact of the child and guardian having to make a second visit in order to save this time is a matter which in many cases entails no little hardship and expense to those who are least able to afford it. The only other argument advanced in favour of the use of ointment or drops at home for several days is the one that unless atropine is used for several days complete paralysis of [illegible] ined in all cases. I have never [illegible] ed by anyone who has given the [illegible] trial, and I am convinced that [illegible] would be satisfied that it is not only unnecessary, but a positive waste of time to do otherwise. For those who have not tried this method I will give a few details as to the use of the tablets.

First of all I may say that I have always used Messrs. Burroughs Wellcome and Co.'s ophthalmic "tabloid" brand of atropine sulphate, and have always found them highly satisfactory, combining as they do all the merits that an ophthalmic tablet should do—namely, speed in dissolving, accuracy of dosage, reliability in action, non-friability in handling, and a power of keeping for a long period, some that I have used having been in stock for several years. I have used the foll ing strengths—namely, 1/500 grain, 1/200 grain, 1/100 grain—and find that the 1/200 grain tabloid is a satisfactory strength for the purpose. The application of ophthalmic tablets to the eyes is, perhaps, the one part of this method which some will at first find difficult, and I hope that a few words on this will not be out of place.

After the routine external examination of the eyes, including the subjective test for distant and near vision, has been carried out, I take two tablets in the palm of my left hand, pick one up with the forefinger and thumb of my [illegible] tablet into the palm of my [illegible] my left forefinger and thumb. [illegible], and at the same time I draw down both lower lids by means of the ring finger of each hand; the tablet is then dropped into the lowest part of each fornix. Should the child tend or attempt to close the upper lids this can be prevented by holding them up with the middle fingers Immediately the tablets are put in the child is asked to look at you, and at the same moment the lids are released; in this way the tablets are successfully entrapped in the fornices by the lower lids. This will perhaps seem a lengthy dissertation on a simple procedure, but by watching some attempt it I have proved that a few words of advice are helpful. By those who find the use of their fingers not so easy, I have had a double-pronged vulcanite applicator made, which Messrs. Burroughs Wellcome and Co. kindly undertook for me, a sketch of which is here shown.



Vulcanite applicator (full size).

With this applicator a tablet may be attracted to each prong leaving one hand free with which to draw down the lids at one and the same time.

My reason for desiring to insert the tablets simultaneously, or as near as possible to this, is that if a tablet is put in one eye and that eye is allowed to close before applying the second to the other eye, it will be found that the child feels the first tablet, "screws up the eyes," and makes it extremely difficult to get the second one in. My reason for wishing to entrap the tablet in the lower fornix is that unless this is done the tablet is apt to ride up on to the cornea and thus cause irritation with copious flow of tears before it is fully dissolved, and in this way it may be washed out of the conjunctival sac on to the edge of the lids

If the procedure is carried out as I have indicated it will be found that the tablet is dissolved almost before the child is aware that there is anything in the eye—in 10 to 20 seconds; very slight smarting is then felt, there is a little pericorneal flush, the pupil dilates fully in from 10 to 15 minutes, and there is a complete paralysis of accommodation in half an hour, at the end of which time I estimate the refraction and order the appropriate lenses. Accommodation is fully restored in from six to eight days. I have now dealt with over 800 children in this manner, and have only once had to apply a second tabloid to get paralysis of accommodation, and in that case it was due to faulty application of the first tabloid, part of which was found on the edge of the lid It is the rarest thing to find any child cry after having put the tabloids in, and those few who have done so have always shown *indications of approaching* lacrymation almost before any attempt at touching their eyes had been made. The younger the children the less trouble it seems to cause them, their ages ranging from 4 [illegible] *tablets to a dozen or more* [illegible] they are generally all smiling [illegible] two have braved the ordeal; [illegible] select your first two children, and if it is a good selection they will probably laugh over the sensation and the rest will follow suit.

I have more particularly wished to give my experience in this method of atropinisation in order to point out the enormous advantage in time and convenience it has over the home use of ointment or drops in dealing with the refraction of school children in school clinics and suchlike centres where many children are collected together at the same time. It necessitates only one visit; whereas with the use of ointment or drops it is the invariable experience, no matter what elaborate instructions, written or otherwise, are given, that at least one or two, and often more, out of every dozen return for refraction, either not having used the ointment at all or only partially so. They are then sent back a second time with a further supply of atropine, which although not used the first time yet in some way has mysteriously disappeared. Then, again, a certain number of the cases do not return at all, whereas if the tablets have been used on the first visit there is no chance of escape from refraction at any rate. The use of atropine at home, too, is not such an easy matter, especially when it has to be done three or four times a day for several days. It requires not only experience but time and patience, and how often, as one knows, the home and mother are already saddled with a hundred and one other duties.

One further point to which I would like to draw attention is that I have not yet seen any case, when using these tabloids, present any signs or symptoms of atropine irritation or poisoning. As regards actual cost of material, the tablet method compares very favourably with that of ointment or solution, the hospital price of the tabloids working out at about 6*d.* for a tube of 25, so that 12 cases can be refracted at a cost of a fraction less than ½*d.* each. Atropine ointment is supplied in two-drachm chip-boxes at a cost of a ½*d.* each, in addition to which a glass rod for application has also to be given, and time spent in the dispensing of the ointment or solution.

London, W.

THE USE OF GELATIN IN MICROSCOPICAL TECHNIQUE.

By W. JOHNSON, M.D. LOND., M.R.C.P. LOND.,
GULL STUDENT, GUY'S HOSPITAL.

AT the Conference of the Sudwestdeutsche Neurologen und Irrenärzte held in Baden-Baden on May 24th and 25th, Professor Edinger (Frankfort-on-Main) showed several microscopical specimens mounted in gelatin in place of the usual mountant, Canada balsam. As I have had the opportunity, while working in his laboratory, of practising this method, I append details for any who may wish to make use of it. The technique has been developed from suggestions originally made to Professor Edinger by a photographic chemist, Mr. Ralph Liesegang, and has been worked out chiefly from the point of view of utilising it for neurological preparations. It is, however, by no means confined to this particular branch, but can be applied to most pathological work.

Sections may be cut by any of the usual methods—viz., freezing, paraffin, or celloidin. They can then be stained in the ordinary way, and all stains are available with the exception of those which can be extracted from the tissues by immersion in water. This group of exceptions is not large, but, unfortunately, it includes Nissl's method and all others in which the aniline dyes figure. Efforts which we made to fix these dyes in the tissues—as, for instance, by the use of solutions of varying strength of ammonium molybdate—preparatory to placing the sections in water, have proved unsuccessful. Further work may possibly overcome this difficulty.

Having completed the staining process the section is put into water and is now without further treatment ready for mounting in the gelatin solution.

In the preparation of this a few essentials must be noted. Firstly, the solution must be freshly made and the best results are only obtained when the special gelatin, as used for photographic plates, is employed. Of this, 10 grm. are taken and allowed to soak for two hours (preferably overnight) in 100 c.c. of distilled water. When about to be used this solution must be warmed to a temperature of 50° C. by means of a water bath in order to render it sufficiently fluid. It is advisable to filter it beforehand, also at this temperature.

As much of this warm solution is then gently poured on to the slide as can be put on without any overflowing. It is important to pour on as much as possible in order to get a sufficiently thick film of gelatin in the final result. When large sections are being treated it is better to keep the slide on a warm stage, and in the case of frozen or celloidin sections to pour on a thin layer of the gelatin solution first before putting the section in position on the slide. Larger sections still can, with profit, be immersed in the solution for a few minutes beforehand. The preparation is now left exposed to the air, and in the course of a few hours the water evaporates and one is left with the slide covered with a fine transparent film of gelatin in which the section is imbedded. This film behaves in every particular like the gelatin film on a photographic plate. It is intensely hard, resists scratching, and can be packed face to face with other specimens without involving the risk of finding them glued firmly together as is the manner of Canada balsam. Under the microscope a perfectly clear picture is given, and if necessary cedar-wood oil, for oil immersion purposes, can be used.

The great advantage of the method is the economy of time and material which results. There is no tedious transferring from dish to dish for the processes of dehydrating and clearing. Thus alcohol, xylol, Canada balsam, and cover-slips are entirely dispensed with, and in addition one does away with the danger of injuring large brain sections which attends too much handling. Apparently specimens will keep indefinitely. Weigert-Pal preparations — for which the method is eminently suitable—have been preserved for three years. Serial sections, which require large slides and cover-slips, lend themselves to this manner of mounting. Finally, perhaps, botanists may find here a useful servant. Their chlorophyll specimens, being untreated by alcohol, are able to retain their pigment unaltered, and so can be mounted in the natural state.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF ACCIDENTAL COAL-GAS POISONING, WITH RECOVERY.

BY WALTER ROBERT S. JEFFERISS, M.D., C.M. EDIN., D.P.H.

AS cases of accidental poisoning from coal-gas are not frequently met with in general medical practice, perhaps the following notes of a case may be of some interest to medical men.

On Oct. 4th, 1912, I was asked to go to the relief of a man over 60 years of age who was supposed to be dying. On reaching the house I found the whole place smelling strongly of coal-gas, and on going upstairs to the bedroom, a room of about 11 ft. square, I found the man lying on the bed on his back quite insensible, breathing stertorously, and to all appearance not far from death. There was also one other occupant of the room, a small grey linnet in a cage overhanging the bed, but it, alas, had sung its last song and was lying dead on the floor of its cage. The man's face was livid; his eyes were wide open, the pupils firmly contracted, and the corneal reflex gone. There was not a trace of consciousness left, and the breath smelt strongly of coal-gas. The bowel sphincter was relaxed; the temperature was slightly subnormal, the body being well covered in bed; and the pulse was 68, regular, and moderate in strength. I had the patient brought close to the open window and resorted to artificial respiration, coupled with cold affusion to the head and flicking the body with a wet towel. Consciousness gradually returning, and the patient being now able to swallow, I gave him some hot, strong coffee, a spoonful at a time, and after an hour's efforts he recovered, and I left him in the charge of his relatives. On the next day, after a good natural sleep, the patient seemed quite himself.

The history of the case is as follows. The patient, who lived with his son, not feeling very well on the previous day, had retired to bed somewhat earlier than usual, the gas being lighted to warm the room as there was no fire. The bedstead blocked the fireplace, the and window were shut, and the gas was allowed to all night, or rather up to a late hour of the night, when the son, as was his custom, turned off the *meter on going* to his own bed, but omitted to turn off the gas-tap in his father's bedroom. The father, seeming tired, continued to remain in bed, and the relatives considering that he was not "up to much" advised him to rest until after dinner-time, which he agreed to do. After breakfast-time the son had occasion for business requirements to turn on the gas downstairs again, forgetting that the gas-bracket had never been turned off in his father's room. During the afternoon the relatives *went upstairs and found the patient* as I have described, *the room full of gas, and the gas-bracket still on.*

This recalls to my recollection an extraordinary case of murder, where the secret opium poisoner used coal-gas to cover up his crime by pretending that his victim (his wife) was dying from accidental poisoning by the escape of coal-gas in her room, and then calling in a medical man, who, at first believing his tale, used similar measures as were used in this case, but finding no success sent for an *expert to assist him, and as a result they considered the* best thing was to remove the patient to a hospital for further treatment and watching. Their efforts were unsuccessful, and the woman died. A post-mortem examination threw no light on the case, but a small stain on her pillow at her own house was analysed and found to be extract of opium. The poisoner attended his victim's funeral, was shadowed, and then arrested, brought to trial, convicted, and hanged at Edinburgh in 1866. In this case *the poisoner had broken through the gas-pipe, which was* behind a shutter in the room, and thus allowed the gas to escape, which he thought would mislead the medical men and cover up his crime.

During the past year or two I have met with two or three would-be suicides who have tried to effect their purpose by using coal-gas inhalations, but were rescued by their relatives in time to prevent a fatal termination to their foolish attempts.

Chatham.

NOTE ON A NEW OPERATION FOR FEMORAL HERNIA.

BY G. S. THOMPSON, F.R.C.S. ENG.

I THINK *it will be admitted that most, if not all, of the* operations for femoral hernia are theoretically if not practically unsound, and therefore leave much to be desired. Simple ligature of the sac here, as opposed to the same proceeding in the inguinal variety, is obviously inadmissible. Muscular obstruction to the canal has not yet readily been effected, as far as I am aware, and its attempt by means of a flap from the pectineus muscle can be only temporary, since the tissue used by being inevitably deprived of its nerve-supply must *degenerate into a fibrous mass, to say nothing* of the objectionable mutilation. This flap method may or may not form an efficient barrier; at any rate, it cannot be relied on with certitude. *Approximation of Poupart's ligament* to Cooper's ligament or the pubic bone by suture, staples, or wire is apt to alter detrimentally the anatomical arrangement of the parts, causing, amongst other things, undesirable pressure inwardly and from above on the vessels to the lower extremity, whilst metal bodies in this region are a possible source of danger, to say nothing of the loosening of such things as staples. Of all these processes a modification of one of the last, by means of a loose suture between the two ligaments arranged in the form of a network, and acting like a filigree by provoking infiltration by fibrous tissue, would appear to be the best.

The means I adopt and will now describe involve the use of a specially but easily prepared celluloid filigree shaped so as to fill the triangular femoral hernial space. I have already[1] drawn attention to the value of celluloid in some departments of surgery, and amongst other things indicated the especial value of a perforated celluloid plate rather than silver wires as a general filigree substance for large and suitable hernias. Several rectangular-triangular pieces of thin sheet celluloid of various sizes and the shape of the femoral canal are cut. The short outer side is rendered slightly concave, the long side corresponds in position to Poupart's ligament, while the third side opposes Cooper's ligament. These celluloid triangles are riddled with perforations by a fine punch, and the *sharp angles thereof are* rounded off. The outer concave border is then turned back at right angles to the remainder, and by means of the thumb-nail the flange thus formed is made to present a concavity *at its junction with the rest* of the plate. Subsequently this flange will be outermost, resting against the vein, and is formed to eliminate the sharp edge that might otherwise ulcerate into the vein and produce disaster. So much for the filigree.

Regarding [illegible] been made o[illegible] and the sac [illegible] rm against the vein a cushion [illegible] ll rest. *The femoral triangle* [illegible] above, *Cooper's ligament* and the bone below, and the vein and connective tissue externally, is then clearly and cleanly defined. A suitably sized filigree is next chosen and inserted into this space and will rest against Poupart's ligament above, Gimbernat's ligament internally, the pubic bone below, whilst the flange opposes the vein externally, from which it is separated by the pad of loose connective tissue already referred to. *Three temporary catgut fixation stitches* are *inserted* through the perforations at convenient spots, thereby fixing the filigree to the above three ligamentous structures. The operation is thereafter concluded. The femoral canal is now completely obstructed and in a short time following the operation the perforations of the plate get riddled by fibrous tissue, as a result of which the plate becomes covered by, and embedded in, the same and thereby firmly fixed *in situ.* By this means the canal is *permanently, thoroughly, and satisfactorily closed without* causing pressure on, or injury and improper disturbance to, the parts; and hence an impassable barrier is constituted. Moreover, the vessels cannot be damaged or interfered with by this plan, and I think the method will prove not only the most but quite a satisfactory means, to the exclusion of all others, of coping with this troublesome condition.

Amongst other things, celluloid has the great advantage of being flexible, and consequently of adapting itself to *every varying* conformation of the part. *Boiling is apt to* crinkle this substance, and therefore it is preferably sterilised by being inserted in alcohol or some antiseptic for some time preceding its use. Celluloid can be obtained in thicknesses varying from that of the ordinary photographic film to cardboard, but for this part of the body the thinner sheets are desirable as forming a resilient and light yet efficient barrier, consisting ultimately of celluloid and its investment of fibrous tissue, which forms a femoral diaphragm.

The same principle as already utilised may be modified and adopted by using a triangular floss-silk or chromic catgut network filigree; and this would constitute an improvement on the plan of constructing *in situ* a mesh by suture of the ligaments of the part—a *manipulation,* as a fact, *not easy of satisfactory accomplishment.* If this modification be preferred or is preferable, several sizes of fine meshed triangles should be constructed and the surplus threads *prolonged from each angle* and *two or more places* from the upper and lower sides for purposes of suspension and fixation. The outer side of this kind of filigree, as in the case of the celluloid homologue, would be concave. The free threads will be used for fixing the netted filigree to the ligaments of the femoral triangle. This net filigree will have *the* same effect as the celluloid plate, provoking, and resulting in, the formation of a fibro-cellular diaphragm superimposed on the artificial septum introduced. As the former would probably be adequate *to obstruct the canal,* an absorbable material like chromic catgut might be sufficient to meet all requirements, *failing* which *floss silk* would be indicated as the substance of choice—a question, however, which time alone can answer.

Kimberley, South Africa.

TINCTURE OF IODINE AS A HOUSEHOLD REMEDY.

BY EDMUND OWEN, F.R.C.S Eng.,

CONSULTING SURGEON TO ST. MARY'S HOSPITAL, LONDON.

IN recent years surgeons have learnt that a quick and easy way of rendering a wound or a surface of skin surgically clean is by painting or swabbing it with fresh tincture of iodine. To make the method quite trustworthy, the part [illegible] of the tincture [illegible] pore or crevice. [illegible] that they also might find the tincture a [illegible] protector; that they ought always to have a small bottle of it close at hand, a[illegible] many a cut, prick, or [illegible] of the dangerous [illegible] lock-jaw. The first-aid man should certainly carry some of it in his pouch, and the cyclist in his wallet. The gardener ought to have a bottle of it within reach, as the germs of lock-jaw live in the soil in which he works. The groom and the horse-keeper should be made fully aware of its value and importance, for the earth of the stable-yard and of the high-road on which they may be wounded is likely to be teeming with these same germs. The school matron should be ready to apply the tincture to the cut finger, the grazed knee, the barked shin, and the kibed heel, and a small bottle of it should be in every workshop and factory. And in the case of a compound fracture, or other grave wound, a pad of wool or linen dipped in the tincture should be placed directly over it, before the *doctor has had the chance of seeing it.*

The first-aid teacher and the health lecturer should call particular attention to the value of tincture of iodine, and should urge its use in such circumstances as those suggested in preference to all other antiseptics, and should explain why it should be applied to the dry surface.

Amongst the many advantages of the tincture is this, that it is not poisonous or harmful as carbolic acid is apt to be, and that it can be applied straightway, without preparation and also without fear of doing any damage.

Upper Berkeley street, W.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A General View of Malingering.

THE thirty-second annual session of this society was opened at the West London Hospital on Oct. 3rd, when Dr. F. S. PALMER was inducted as the new President. The "Keetley Memorial Medal" was presented by the President to his predecessor in office, Dr. G. P. Shuter, to whom a very hearty vote of thanks was accorded.

Dr. PALMER then delivered his presidential address, entitled "A General View of Malingering." The term malingering, derived from the French adjective *malingre*—weakly or sickly—had [illegible] much wider application [illegible] the word included the *suppressio veri* as well as the *suggestio falsi*, and the reason probably was that there was no essential difference between the simulation of disease to extort money from an employer and the deliberate concealment of known ill-health to defraud a company or corporation. Formerly it was chiefly encountered in the army and navy, among prisoners, and the inmates of hospitals and workhouses, but recently it had become more general, particularly among industrial workers. Among the influences which promoted malingering was the trend of modern legislation. Since the Workmen's Compensation Act of 1906 came into operation the number of claims had gone up by leaps and bounds, and precisely the same experience was reported from France and Germany, where the accident laws were older than our own. Employers had discovered that it was cheaper to settle claims out of court than to contest them. Although the activities of some speculative lawyers and so-called legal aid societies stirred up strife between employers and employees and encouraged malingering, it was a mistake to suppose that the enormous increase of claims admitted by most of the Approved Societies was due entirely to malingering. The National Insurance Act had opened a new and perilous chapter in history and unlocked the floodgates to the risk of malingering on a scale hitherto unknown. Six months' working of the Act had shown that the sickness claims of women were amazing. The desire to get something back for what had been paid was a human failing. The logical sequence to compulsion was resistance, and that it would take the form of malingering in many instances was a certainty. The psychology of malingering was a complex and interesting study; pecuniary gain was not always the underlying motive, and other influences were often at work, such as idleness and a desire for sympathy or notoriety and resentment. Hitherto, the largest proportion of claims were for the results of accident or injury, and extravagant damages were often demanded from wealthy employers, corporations, or the State. Many persons fit to return to work were restrained from making the attempt when litigation was in the air by the fear that it might prejudice the issue. Introspection, suggestion, repeated medical examinations and consultations with solicitors, according to the psychological law, led to the intensification of symptoms; and so long as these mischievous agencies continued in operation the abnormal mental condition was not likely to improve. Although it was the duty of the profession to discountenance any kind of fraud which came under notice, no doctor was expected to undertake the duties of a detective. If he acted in good faith not much was to be feared, and no sensible medical man would make an accusation of malingering unless he was prepared to bring forward positive evidence in support of the charge. Precipitate action was to be condemned. In doubtful cases it was far better to be deceived than to allow unjust suspicion to fall on the victims of some obscure or depressing disease. The essential feature of malingering was deliberate deceit to gain some desired end. Valetudinarianism occupied a different position. The President then considered the various methods of malingering. Valetudinarianism was of great importance from the medical standpoint. Many of these cases, no doubt, came under the head of unconscious or subconscious malingering, but it also included a considerable proportion of genuine invalids who demanded the utmost sympathy and protection. Surgical cases gave far less trouble than medical ones; there was not much scope for fraud in visible physical injuries. When objective signs were present they could be deciphered on regular lines, but if the complaints were only subjective one had to rely on the none too reliable statements of the claimants. Some of the so-called functional cases deceived the very elect. Before a diagnosis of functional disease could be made organic signs must be eliminated from the field of inquiry. The sufferings of the true neurasthenics were only too sad and genuine, and to brand them with the name of malingerer was both cruel and unjust. Finally the President dealt with the prevention [illegible] suggestions: [illegible] referees of [illegible] with the arbitrators or county court judges to interpret medical evidence; (3) a system of organised lay inspection and visitation; (4) compulsory detention in hospital of doubtful cases; (5) a time limit to functional illnesses; (6) periodical medical examination of suspected cases by independent practitioners; and (7) some system of registration by which the benefits of claimants from all sources could be made known.

During the evening cases were shown by Mr. N. BISHOP HARMAN, and the meeting closed with a vote of thanks to the President for his interesting and opportune address.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 3rd. Dr. David Ross, the new President, delivered an address on Some Mistakes in Prognosis. He urged the advisability of not giving a prognosis on seeing a patient for the first time, although one was often demanded, especially from a consultant. An absolutely hopeless prognosis should seldom be given. He doubted whether the date of demise could be fixed by anyone, illustrating the unwisdom of attempting to do so by a case of heart disease in a woman who was given three weeks to live, yet who on hearing the opinion changed her attendant, and three months later became a weekly attendant at the local theatre for about two years. Prognosis depended on a complete and careful examination leading to a scientific diagnosis. Yet the disease should not alone be considered and weighed, but the body as a whole in which it occurred. In bedridden asthenics death was not infrequently delayed though desired. Conversely, some apparently died merely because death was expected by the patient, the illness being but an excuse for the end. To illustrate recovery from the moribund state a puerperal septicæmia was cited in a young woman to whom no good from vigorous treatment resulted. Then morphia in a moderate dose was hypodermically injected, and, to the surprise of all, sleep succeeded delirium and a gradual convalescence was followed in due course by five pregnancies. Arthritis due to pyorrhœa alveolaris was not invariably cured by the removal of the cause, but might unexpectedly increase. A case of malignant disease of the base of the bladder, seen by a consultant, in a man aged 70, was given an unfavourable prognosis, yet after treatment by ergot and calcium chloride hæmorrhage and retention of urine gradually ceased. Now, three and a half years after the diagnosis was made by the aid of the cystoscope, the man goes twice weekly to the city on business Prognosis in pulmonary tuberculosis he considered full of difficulty, quoting a case of a young man who seemed to be dying and so to justify an unfavourable opinion. Yet he speedily improved, and is now, four and a half years from then, in active business. When honestly possible a favourable outlook should always be given because of its therapeutic effect. A bad prognosis by destroying hope and paralysing sustained effort might *often bring about its own fulfilment.*

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on Oct 1st. Dr J. J. Graham Brown delivered the opening lecture and took as his subject "Certain Aspects of Hemiplegia." His object was to prove that the movements regained on the paralysed side after hemiplegia were due to the re-assumption by the basal ganglia of functions possessed by them before the development of the phylogenetically recent cortex. He briefly reviewed the history of the cortex from the standpoint of comparative anatomy, tracing it from the ganoid fishes through the reptiles, birds, and lower mammals. He then showed that complete ablation of the cortex in these fishes, reptiles, birds, and lower mammals was followed by little or no effect at all, owing to the fact that in these animals the cortex was of such recent appearance that it had not taken the functions of movement and locomotion from the basal ganglia to any great extent. In man, however, most of these functions had been abrogated to itself by the cerebral cortex, although it was probable that the basal ganglia even in his case retained some of their primitive functions as far as locomotion and perception were concerned. He quoted a case of great interest that had come under his observation in which the patient who had hemianopsia was able to state in which direction an object was moved, the blind side being stimulated, although he was unable to "see" it. Dr. Brown then discussed the theories at present accepted as to the factors at work when movements return to a previously paralysed side. He could not agree with the statement that the homolateral cortex was the agent owing to the fact that movements returned after a double hemiplegia Neither could he accept the theory that such movements were due to the direct *pyramidal tract*, since the fibres of this tract almost certainly decussate in the cord before passing to the cells of the [illegible] cipal [illegible] the [illegible] and [illegible]

NATIONAL ASSOCIATION FOR THE FEEBLE-MINDED.—In the council chamber of the London Guildhall on Oct. 23rd Field-Marshal Lord Methuen will preside over the annual Conference on After-Care. The Lord Mayor will open the conference at the morning session which commences at 10 45, and a paper by [illegible] Chance on the Mental Deficiency Act, 1913, [illegible] President's address. At the afternoon session [illegible] at 2 o'clock, papers are announced by Mr. F. O. Spensley, senior medical officer at the Darenth Industrial Colony, on Occupations Inside Institutions, and by Mrs. Burgwin on Occupations Outside Institutions. There will be a discussion at each session, and work done by feeble-minded inmates at various homes and institutions [illegible] day. In view of the importan[illegible] there will be a [illegible] bodies concerned in the [illegible] report of the proceedings will be issued at the price of 1*s.*

Reviews and Notices of Books.

Surgery, its Principles and Practice. By Various Authors. Edited by WILLIAM WILLIAMS KEEN, M.D., LL.D., Emeritus Professor of the Principles of Surgery and of Clinical Surgery [illegible] Philadelphia. Vol. VI., with [illegible] them being in colour. London and Philadelphia: W. B Saunders Company. 1913. Pp. 1177. Price, cloth, 30*s.* net.

THE fifth volume of this "System of Surgery" completed the work, and that volume was published in 1909, but the time that has elapsed since then has witnessed so many advances in surgical theory and practice that the editor felt it was desirable to publish a supplementary volume, in which might be included all the latest facts in surgery. The authors of the articles in the previous volumes were therefore asked to provide the extra material, so as to bring their articles up to date; in addition, a few new sections have been added on intratracheal insufflation, the surgery of the hypophysis or pituitary gland, and the use of salvarsan in syphilis.

From the very nature of the volume as a supplement to the "System of Surgery" it follows that many of the articles are brief and, in fact, even a little scrappy, for only those points which are new are recorded; but this in no wise detracts from the value of the volume, for it is these new points which are of importance It is somewhat invidious to select from so large a mass of material articles for special mention, but there are some which seem to us particularly valuable The chapter on shock, by Dr George Crile, of Cleveland, is a very useful summary of his views on this important matter, and as he has probably done more than any other surgeon to advance our knowledge of this condition, this presentation of his views is likely to prove useful. The chapter on what he has named "*anoci-association*" is a careful account of his methods of avoiding post-operative shock in all its forms, and will be familiar in its contents to readers of our columns. The article on fractures, by Dr. Daniel Eisendrath, of Chicago, also contains much new material.

The new chapter on the surgery of the hypophysis has been written by *Dr. Dean Lewis and Dr. Allen Kanavel*, of Chicago; it contains a satisfactory account of the development, the anatomy, and the histology of the gland, and its physiology, at least so far as that is known The symptomatology connected with the pituitary body and the operative treatment which has been employed for tumours affecting it are detailed, thus forming one of the best accounts of this gland and its diseases that we have seen. Dr. George Emerson Brewer has written on the surgery of the thorax, and as this is a department of surgery in which much recent progress has been made the chapter is long. Mr. Mayo Robson's article on the surgery of the stomach certainly merits special mention, *as does also* the chapter on the surgery of the intestine by Dr. Weller Van Hook and Dr. Allen Kanavel, of Chicago. We should also like to draw attention to the chapter on plastic surgery by Dr. John B. Roberts, of Philadelphia.

The editor has wisely added a general index to the [illegible]

British Rainfall, 1913. By H. R. MILL, D Sc, Director of the British Rainfall Organisation; assisted by CARLE SALTER. With Maps and Illustrations. London: Edward Stanford. 1913. Pp 468. Price 10*s*

THIS invaluable work continues to increase in scope and [illegible] the number of stations at which observations are [illegible] increase of 193 over [illegible] stations by counties and river basins throughout the United Kingdom is now complete, and useful maps are supplied in this volume.

clearly indicating the basins and watersheds. The mean rainfall for stations in England in 1912 was 39·31 inches, being 23 per cent. above the average of the 35 years, 1875–1909; in Wales it was 56 19 inches, or 19 per cent above the average; in Scotland it was 49·01 inches, being 11 per cent above, and in Ireland 44·06 inches, or 8 per cent. above, the average. Within the last 32 years for which comparisons are available, two only (1882 and 1903) have been wetter than 1912 in England and Wales, or in the British Isles. In 1910, for the first time in 21 years, a wet year immediately followed a wet year, and the succession of two dry years followed by one wet year, that had been the rule in England and Wales from 1889 to 1909, broke down. Dr. Mill points out, nevertheless, that it is significant that the very wet year 1912 "falls into place in the old order, maintaining the tradition that every third year should be wetter than the two preceding." The greatest rainfall in the kingdom occurred on Snowdon (Crib Goch), where 205 17 inches were registered; in England 196·43 inches fell at the Stye, near Scafell Pikes, in Cumberland; in Scotland 178·95 inches fell at Loan, Loch Quoich; and in Ireland 106·60 inches were recorded at Gearahameen in the Gap of Dunloe. The least rainfall, 19 24 inches, was registered at Stifford (Essex). The principal feature of the year was the great rainstorm of August 25th and 26th, extending over a considerable part of East Anglia, where a fall of over 3 inches occurred in Norfolk and Suffolk and Cambridgeshire; in East Norfolk and the adjoining part of Suffolk more than 4 inches fell, while in the neighbourhood of Norwich the fall was over 7 inches, at one point (Brundall) 8·09 inches, and at another (Sprowston) 8·25 inches being recorded in these two days. This is the heaviest rainfall hitherto recorded in the British Isles, that at Seathwaite in 1897 having reached only 8 03 inches. Disastrous floods were the inevitable result, the effects of which on the public health have probably been long-continued and far-reaching. We much regret to hear of the ill-health of Dr. Mill, whose eyesight has been so much affected by the constant strain of this work that he has had to take complete rest for a considerable period. It is also regrettable to learn that, although the expenditure on the organisation amounted to £1521, the receipts only came to £1409, the considerable deficit of £112 having to be met by the honorary director himself. If municipal bodies and sanitary authorities understood the value of this organisation and its important bearing on public health questions, we cannot help thinking that more of them would give their support. Only 19 of these public bodies throughout the country subscribe to the organisation.

Syrian Anatomy, Pathology, and Therapeutics, or "The Syrian Book of Medicines." The Syriac text edited from a rare manuscript, with an English translation by E. A. WALLIS BUDGE, M.A., Litt D. Vol. I.: Introduction, Syriac Text. Vol II.: English Translation and Index. Oxford University Press, London, New York, Toronto, Melbourne, and Bombay: Humphrey Milford. 1913. Vol. I., pp. clxxviii.–612; Vol. II., 804. Price 42*s.* net.

THE science and art of medicine owe a heavy debt to Syrian Christianity, theologically known as Nestorianism. For it was Nestorian Christians, whether Arabs or Syrians, who in the great schools of Gundisapor and Bagdad studied and translated into Arabic or Syriac from the sixth to the ninth century A.D. the works of Hippocrates and Galen. Such students were Sergius Rish Aina, Bachtishua, and the Mesues, who were Syrians, but the greatest of the translators was Hunain, a Christian Arab, who was assisted by his nephew Hubaish. The Nestorian Church in its palmy days had an organisation which stretched from Asia Minor to China, and the Nestorian physicians were widely known and valued. We learn from Mandeville that the Great Cham of Tartary had: "Of Phisicyens Cristene 200. And of Leches that ben Cristene he hath 210. And of Leches and Phisicyens that ben Sarrazines 20, but he trusteth more in the Cristene Leches than in the Sarazines." It is almost certain that these "Cristene Leches" were Nestorians. Gundisapor was founded, as its name implies, by Sapor I. (A.D. 240–273), and he imported thither Greek physicians, who in the words of Bar Hebraeus "sowed Hippocratic medicine in the East." Thither, too, after the break up of the great medical Syrian school at Edessa, which was closed by the Emperor Zeno in 489 A.D., came various Nestorian physicians, such as Sergius of Rish Aina, who translated portions of Galen. He died about A D. 536. The last of the great Syrian physicians was Bar Hebraeus, who died in 1286.

Syriac works on medicine are rare, and Dr. Budge has conferred a great benefit on students of historical medicine in thus laying before them a book which, as he says, is "the most important and most perfect Syrian treatise on anatomy, pathology, and therapeutics known to us." The manuscript which he had copied, and the text of which is reproduced in these volumes, was written, he considers, in the twelfth century. It is unfortunately incomplete, for the first portion commences with Chapter III. and portions in the middle and at the end are also missing. This first portion deals with anatomy, pathology, and therapeutics. The second portion deals with astrological matters, and the third, entitled "The Book of Native Medicines," is a collection of popular recipes and prescriptions evidently drawn up by "physicians" who did not adopt the Hippocratic theories which are the foundation of Section I. Dr. Budge considers that the first two sections were probably originally written in Greek, while the third "may have been written in Arabic, or Persian, or in some Syrian dialect."

Section I. is a series of lectures in which the author, whoever he was, follows the principles laid down by Hippocrates and Galen. The various portions of the body and the diseases which affect them are dealt with seriatim, commencing with the head; the last chapter, which is incomplete, begins with diseases of the kidneys. Numerous personal experiences are quoted in illustration of the principles laid down in the lectures, and the author had evidently seen many dissections performed or had dissected himself, for he constantly refers to anatomical points apparent by dissection. Also, he insists on the value of anatomical knowledge for a right diagnosis and successful treatment. Here is an illustrative case (Vol. II., p. 131): "If therefore a man knoweth from the making of dissections the sources of the nerves which come to each one of the members, this man, I say, can cure so successfully the want of feeling and the want of motion of each one of the members, even as I myself did in the case of a man who fell from a horse, and hurt the upper part of his back, and feeling was paralysed in two of his fingers and the half of a third. I ordered them to put plasters on the place which was injured, and the man was cured in a few days. And with the following fact physicians are not all acquainted that the roots of the nerves which are divided (i.e., radiate) in the skin of the hand, wherefrom cometh the power to feel, are of one kind, and that those which move the muscles are of another." The author of the "Book of Medicines" must have felt an honest pride in this case, for Galen relates an exactly similar case with the exception that his patient had fallen from his chariot and not from a horse. (De Locis Affectis, Lib. I.; see Kuhn's "Edition of Galen," Vol. VIII., p. 56 *et seq.*) It must not be imagined that the author exhibits such sound knowledge as the above in all his lectures, for, as is only natural in the state of physiological knowledge of that time, he is inclined to treat symptoms rather than causes, of which he was necessarily more or less ignorant. But as regards nervous affections and paralyses, wherein, as we have seen, he applies correctly his anatomical and physiological knowledge, he lays down the canon (p. 143) "If a man is not able to make a diagnosis he will not be able to cure the disease properly." On the whole his lectures are far more scientific than the writings of many physicians of the thirteenth and fourteenth centuries, and there is a singular absence of the loathsome prescriptions which are so prominent a feature of later writers, even of the seventeenth century.

In addition to his translation Dr. Budge has supplied a most interesting introduction, giving a description of the MS., a *précis* of the contents of the three sections, a short historical review of ancient medicine, and a chapter dealing with the author so far as anything can be gathered from his work, which is but little. The date of the "Book of Medicines" must be as late as the second century A.D., as Galen and Sorinus (probably Soranus of Ephesus, 98–138 A.D.) are quoted. But the book is, in the main, Hippocratic, and it is one which every student of the history of medicine should study. It is published under the direction of the Royal Society of English Literature of the United Kingdom.

A Course in Normal Histology: A Guide for Practical Instruction in Histology and Microscopic Anatomy. By RUDOLPH KRAUSE, a o Professor of Anatomy at the University of Berlin Translated from the German by PHILIPP J. R. SCHMAHL, M.D., New York. Part I. London: Rebman, Limited. 1913. Pp 86 Price 5*s*. net.

THE slim volume before us, containing only 86 pages of text, is devoted to the technique of histological study. It is published separately in order that it may prove of use to others besides students of histology, affording as it does an epitome of microscopical methods.

It opens with an account of the structure and principles of the microscope itself, in which are described the properties of lenses, single and in combination, the methods of illumination adopted in modern microscopes, and the structure of the stand itself. Such terms as achromatic and apochromatic are explained, and the principles of immersion and of the construction of objectives are elucidated. A few words of advice are added as to care of these instruments, of which the cost of one suitable to a beginner is given as 300 to 400 marks (£15 to £20). The next section deals with methods of preserving specimens and with the principles of cutting and staining sections, the various fixatives being enumerated and discussed. The author speaks especially highly of corrosive sublimate, and also favourably of formalin, for this purpose. Among methods of cutting sections a good deal of space is devoted to the freezing microtome, which is evidently a favourite with the author for general purposes. The principles of staining are next set forth, the reader being introduced to mordants and lakes, to progressive and regressive staining, to basic and acid stains, and so forth, and the commoner dyes are enumerated and separately discussed, attention being directed to methods of impregnating tissues with silver or gold and to the mode of injecting organs. Finally, a few pages are devoted to mounting specimens and to measuring and drawing them when finally prepared. Professor Krause rightly lays stress on the importance of every student practising the methods here set forth and not being content to receive specimens ready prepared by a demonstrator, as well as on the value of making drawings of what is observed.

The book forms a very complete guide to histological methods, a large amount of information being compressed into a small compass. The information given is clear, succinct, and accurate. The translation is of only moderate quality, the translator being apparently not quite at home in the English language. For example, we do not usually speak of alcohol "assiduously" attracting water, or of the paraffin method of embedding tissue as the most "aggressive" (does this mean "troublesome"?) Phrases such as "a different colour than ......," "most all will be bleached" (for "almost"), "lest the cement will not adhere," are actually ungrammatical. German compound words like "chlor-calcium," "indig-white" should surely be translated by their English equivalents.

Gynæcological Diagnosis and Pathology. By A. H. F. BARBOUR, M D. Edin, LL D. Toronto, F.R C P. Edin, Lecturer on Gynæcology in the University of Edinburgh, Gynæcologist to the Edinburgh Royal Infirmary; and B. P. WATSON, M.D, F.R C S. Edin., Professor of Obstetrics and Gynæcology in the University of Toronto. With 8 plates and 202 figures. London and Edinburgh: William Green and Sons. 1913. Pp. 220. Price 7*s* 6*d*. net.

IN this book the authors do not profess to give a complete account of the various conditions that constitute gynæcological pathology; their object has been rather to furnish the student with a method of study. In their opinion gynæcological teaching in the past has suffered from the fact that the student has not been led to the study of actual specimens and the results of microscopical examination. This is, however, by no means the case in all medical schools; there is, at any rate, one school within our knowledge in which *systematic instruction in gynæcological* pathology has been a prominent feature of the teaching for many years past. If such a defect in the teaching of gynæcology is really common, the fault lies to a large extent with the examiners in the subject, who do not require their candidates to show a knowledge of the macroscopic and microscopic anatomy of gynæcological specimens. A perusal of this book, however, will go far towards putting the student on the right path, and the large number of illustrations should prove of great value in showing him what he is to look for and observe. The book contains a straightforward and clear account of the most important pathological conditions met with by the gynæcologist.

We are glad to see that the authors have given up the old term chronic endometritis; as they point out, this is really not an inflammation of the endometrium, as the name suggests, but includes such conditions as glandular hyperplasia, hyperæmia of the stroma, fibrosis of the stroma, and thickening of the vessels In view of this fact it is a pity that they still retain the names glandular *endometritis* and hæmorrhagic endometritis in the legends to the figures they give. This, however, is a minor detail in a very good book which cannot fail to be of great value to the student who honestly studies it. The section dealing with methods of diagnosis, more especially that part of it treating of physical examination, is particularly good, and the tables of the conditions to be found in the vagina and fornices on carrying out a bimanual examination should prove useful to the student.

LIBRARY TABLE.

A Laboratory Manual of Invertebrate Zoology. By GILMAN A. DREW, Ph D., Assistant Director of the Marine Biological Laboratory, Woods Hole, Massachusetts. Second edition, revised. London and Philadelphia: W. B Saunders Company. 1913. Pp. 213 Price 6*s*. net.—In reviewing the first edition of this book six years ago we commended the orderly manner of its arrangement and the prominence accorded to the salient points. The present edition contains descriptions for the study of a few forms and a rather simple bibliographical list that were not included in the first edition.

The number of pages has been increased with a corresponding ncrease of 1*s*. in the price of the book. The manual is a time saver both for teacher and student.

Woman, Marriage and Motherhood. By ELIZABETH SLOAN CHESSER, M.B. London: Cassell and Company. 1913. Pp. 287. Price 6*s*. net —A volume with such a title naturally arouses nterest. The subject is one that might have been discussed n a superficial manner, annoying to the thoughtful public, or with a wealth of learning or detail deterring to all except the expert student of sociology. Dr. Chesser has steered between the two extremes, and has been eminently successful n producing a book which will probably be widely read by he public. She has a sane, healthy outlook on social problems, on the work suitable for women, and she writes in a fluent, bright style which conceals by an appearance of ease much that is the product of wide reading and close thought. Though fearless and outspoken in her description of the danger to the community and to the individual proceeding from prostitution and venereal disease, Dr. Chesser efrains from the screeds encountered in the publications of unbalanced and emotional writers of both sexes. Dr. Chesser claims that she seeks for the sources of wrong and suffering, nstead of dealing merely with the effects; hence she seeks for the cure of the social evil in the education of the boy and girl, in the care of the feebleminded, in the prevention of alcoholism, and in the amelioration of conditions of poverty. There is much that is provocative of discussion; there is much with which the social reformer would disagree. There is also much that is but theory and generalisation, but the book is one which can be read and considered with advantage to the home and to the development of the average young woman.

MISCELLANEOUS VOLUMES.

SEVERAL reports of learned societies and reprints of original communications and addresses have reached us during the month, which for reasons of space must be dealt with briefly. In some cases the works appeared originally in our columns.

Volume XVII of *Studies from the Rockefeller Institute for Medical Research* (New York: Published by the Institute. 1913. Pp. 624) continues its collections of reprints from various scientific and medical journals of work done by the workers in the laboratory. The list is too long to enumerate, but the volume contains, among many valuable and interesting papers, the original communications of Hideyo Noguchi on the Cultivation of the Spirochætæ, and on Treponemata, papers by Simon Flexner and others on Poliomyelitis, by J. B. Murphy on the Transplantability of Malignant Tumours to the Embryos of a Foreign Species, by Alexis Carrel on Permanent Intubation of the Thoracic Aorta and on Pure Cultures of Cells, besides many papers on Physiology and Pharmacology, Chemistry and Biochemistry, and Experimental Biology. There are also many studies from the Hospital of the Rockefeller Institute in regard to Syphilis, Pneumonia, and Heart Diseases and Conditions.——*The Transactions of the Ophthalmological Society of the United Kingdom*, Vol XXXII. (London: J and A. Churchill. 1913. Pp. 242. Price 12*s*. 6*d*. net), contain, besides the usual official information, the communications brought before the Society during 1912–13, divided under the following heads: Discussion on Vascular and other Retinal Changes in Association with General Disease, papers by James Taylor, Louis Werner, and George Coats; Diseases of the Eyelids and Conjunctiva, papers by [illegible] C. Killick, and Leslie Paton; Dis[illegible] by F. A. Juler, Charles Wray (2); Diseases of the Cornea, papers by Sydney Stephenson, Charles Wray (2), and A. S. Worton; Diseases of the Uveal Tract, papers by Charles Wray (2), Malcolm L. Hepburn (3), and Inglis Taylor; Diseases of the Retina, papers by A. W. Ormond (2), J. B. Lawford, and E. W. Brewerton Diseases of the Nervous System, papers by James Taylor and Gordon Holmes (2), A. W. Ormond, E. Arthur Donnell, and J. F. Cunningham; [illegible] papers by E Treacher Collins and [illegible] E. Treacher Collins, A. C. Hudson (2); Glaucoma, papers by E. Treacher Collins, Arnold Lawson; Muscles and Refraction, papers by N. Bishop Harman, Ernest E. Maddox, E. W Brewerton, H. B. Grimsdale and C. J. Hope Gunning.——*The Proceedings of the Chelsea Clinical Society*, Vol. III. (London: *The Medical Magazine*. 1913. Pp. 124), are edited for the council by J. FOSTER PALMER. Besides the usual official information they co[illegible] Ionisation or Cataphoresis, by [illegible] ment of Phthisis by the Induction of an Artificial Pneumothorax, by Leonard Colebrook; Diseases of the Skin in Relation to Cardiovascular Disturbances, by David Walsh; the Position of Salvarsan in Therapeutics, by H. Wansey Bayly; the D[illegible] Treatment of Neurasthenia, by J. [illegible] Nature and Treatment of Neurasthenia, by Gordon Holmes; Puberty and the Menopause in their Bearing on Neurasthenia, by H. Macnaughton-Jones; Neurasthenia in Relation to Internal Secretions, by Leonard Williams; Neurasthenia in Relation to Eye-strain, by Ernest Clarke; the Work of a Tuberculin Dispensary, by Vivian B. Orr; the Use of Tuberculin in Diagnosis and Treatment, by J. H. Halls Dally; and the Preparation and Standardisation of Tuberculins, by Frank Curry. Several of these papers were published in our columns.——The *St. Thomas's Hospital Reports*, Vol. XL. (London: J. and A. Churchill. 1913. Pp. 217. Price 8*s*. 6*d*. net), are edited by Dr. J. J. PERKINS and Mr. C. A. BALLANCE. They contain for the most part an analysis of the practice of the hospital in its various departments. To these is added the Salter Research Report, 1911: On the Action of Certain Drugs, Toxic Bodies, Toxins, and Micro-organisms on the Fragility of the Red Blood Corpuscles of Man and Animals, by W. W. C. Topley, M B. Cantab, M.R C.P. Lond.——We have also received Vol. XXXI. of the *Transactions of the Royal Academy of Medicine in Ireland* (Dublin: John Falconer; London: Baillière, Tindall, and Cox; Edinburgh: James Thin; Bristol: John Wright and Co. 1913 Pp. 493), edited by J. ALFRED SCOTT, M A., M.D., F.R C.S.I. The Proceedings of this Academy are reported in abstract in our columns.——We have also received bound copies of two lectures: the Bradshaw lecture of Dr. DAVID BRIDGE LEES on the *Diagnosis of Incipient Pulmonary Tuberculosis* (London: H. K. Lewis Price 5*s*.), published in THE LANCET of Nov. 9th, 1912, and commented on in a leading article in that issue; and the Samuel Hyde Memorial Lectures, by Dr. WILLIAM GORDON, on *The Place of Climatology in Medicine* (London: H. K. Lewis. 1913. Pp 62 Price 3*s*. 6*d*.), which appeared in our columns on June 14th and 21st, 1913.

In *A Romance of Filey in the Days of Cromwell* (London: John Long, Limited. Pp. 63), "CAN POINT" tells in the iambic tetrameter of Sir Walter Scott the love story of a noble hunchback for the Lady Sylvia. The author is a medical man.——Few medical men have the time, even if they have the mood or capacity, to work out in literary form such visions of the future as Dr. W. WINSLOW HALL foreshadows in *The Peacemaker, a Retrospective Forecast* (London: A. C. Fifield. 1913. Pp 63. Price 1*s* net). The book is in the form of a drama in three acts, with intercanticles. The characters represent personifications of the nations, and Dr. Hall reiterates the teachings of self-effacing love inculcated by all the great religions. The ideal set forth is doubtless an eminently desirable one, but we find little evidence that human nature has yet evolved to a sufficiently high plane to render it attainable. The author's vocabulary is sometimes astonishing.

JOURNALS AND MAGAZINES

L'Hygiene—The September number of this admirable illustrated journal (MM Manzi Joyant et Cie, 24 Boulevard des Capucines, Paris) contains a very interesting article by Dr Horace Blanchon, entitled "Les Dispensaires d Hygiène Sociale," in which he deplores the ravages of tuberculosis in France and maintains the absolute necessity of founding dispensaries at once for its prevention An anonymous author, above the signature "XXX, contributes *an interesting* description of the epidemic of typhoid fever in Avignon last year Dr Linossier writes with a clever blend of the scientific and popular spirit upon what he terms alimentary anaphylaxis, Dr Maurice de Fleury, Dr Rochu Mery, and Dr Henri Meurisse *are among the other contributors* M Philéas Gilbert contributes the usual article on the cuisine of the month

The American Journal of Tropical Diseases and Preventive Medicine New Orleans The American Journal of Tropical Diseases Company Limited Subscription (countries in the Postal Union) $2 50 a year, single copies, 20 cents—We have received the August and September numbers (Vol I, Nos 2 and 3) of this new periodical, edited by Dr Creighton Wellman, which is the official organ of the American Society of Tropical Medicine We commented in THE LANCET of August 23rd p 579 on an article that appeared in the first number The numbers now before us consist largely of papers read before the last meeting of the association In the August number Dr Victor G Heiser writes on Further Experiences with Beri beri in the Philippine Islands, Major Weston P Chamberlain, U S Army Medical Corps on the Character of the Rice which Prevents Beri beri and the Manner in which it is Milled; Dr Creighton Wellman and Dr C C Bass on Polyneuritis Gallinarum caused by Different Foodstuffs, with Special Reference to the Effect of Commercial Rice-Coating on Neuritis Production, in which the authors arrive at the final conclusion as the result of a series of experiments that "there is more argument against the sale of these common articles of diet sago Irish potatoes and corn starch, than there is against the sale of rice, 'polished' or 'unpolished' milled or undermilled', Dr Carl Lovelace on Peripheral Neuritis in the Amazon Valley; Dr Bailey K Ashford on Sprue in Porto Rico and the Results of Treatment by Yellowed Santonin in which the conclusion is arrived at that santonin does not seem to be superior to a carefully supervised diet, especially a milk diet, and Dr Juan Guiteras on the White Race and the Tropics In the September number Major Eugene R Whitmore, U S Army Medical Corps, discusses Free-living and Parasitic Amoebæ and their Relation to Dysentery, Edward O Jordan, Ph D, writes on Disease Carriers among School Children (a paper read before the International Congress on School Hygiene, Buffalo September, 1913), Frederick Knab on Anopheles and Malaria, Dr Parker Hitchens on Serums and Vaccines in the Prevention and Treatment of Undulant Fever, Dr Charles C Bass and Dr Foster M Johns on the Cultivation of Malarial Plasmodia (Plasmodium Falciparum) in Vitro in the Blood of a Diabetic without the Addition of Dextrose in which it is shown that whatever influence dextrose—and this seems to be essential *for* the cultivation of malarial plasmodia in vitro—has on such cultures may also be produced by the blood sugar of diabetes A curious case is recorded of a diabetic of three years' standing who last July contracted malaria in Central America The fever and malaria persisted in this case in spite of sufficient quinine to control the usual case of malaria The authors suggest that this may have been influenced by the increased amount of dextrose in the *blood* stream

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) RHODALZID (2) PERUGEN (3) VESICÆSAN AND (4) SILVER NITRATE AMPOULES

(CHEMISCHE FABRIK REISHOLZ ACTIES REITMEYER AND CO 63, CRUTCHED FRIARS LONDON E C)

1 Rhodalzid is a combination of the thiocyanate group with albumin, which it is suggested replaces the ordinary thiocyanates with therapeutic advantage *The thiocyanates* have been used in medical practice for the acute pains of tabes and also in arterio-sclerosis and migraine They appear in fact, to have a definite analgesic action but some observers have stated that the inorganic thiocyanates or sulpho cyanides have a disturbing effect upon the alimentary tract and rhodalzid is the outcome of these observations It is in short, an organic thiocyanate which is said to be free from secondary effects There is a suggestion that the presence of thiocyanate in the saliva is opposed to *caries, and the thiocyanates have been used in* caries and stomatitis Rhodalzid is hygroscopic the tablets submitted to us being quite soft, but apparently this does not lead to decomposition Rhodalzid strikes a fine red chestnut colour with ferric salts The tablets yielded no mineral salts on *incineration so we may conclude that* metallic thiocyanates were absent 2 Perugen is described as a synthetic balsam of Peru It contains at least 60 per cent of cinnamein, the normal constituent of the natural product It is employed in skin diseases depending upon *the attack of a parasite It has been used particularly* in scabies and as an antiseptic for wounds In these applications however the natural product has been known to produce disturbance of the kidney function, albumin appearing in the urine For perugen it is definitely claimed that no such action occurs 3 Vesicæsan is prepared from the leaves of *uva ursi*, the decoction having had some repute in the treatment of chronic cystitis and vesical catarrh The leaves contain a definite crystalline principle arbutin which is a glucoside Vesicæsan is prepared by a special process of extraction by which certain principles which are irritating in the digestive tract or the kidney are eliminated In addition vesicæsan is much more acceptable to the palate than the ordinary infusion of bearberry leaves 4 We have examined the contents of the silver nitrate ampoules, the solution being prepared at a definite strength suitable for application as a prophylactic in ophthalmological practice The solution being hermetically sealed keeps the desired strength With the ampoule is supplied a pipette which is plugged loosely at its pointed end with a wad of cotton wool The cotton wool projects somewhat so that in applying the drops to the eye any contact of the glass edge of the pipette ought to be avoided

BAD EMS SALTS

(HERTZ AND CO 9 MINCING LANE, LONDON E C)

The salts of the thermal *springs at Ems in Hessen-Nassau* Germany, are quite simple in character They consist principally of sodium bicarbonate and sodium chloride Other salts occur, but in smaller quantities Routine treatment at the spa has shown the value of these waters chiefly in catarrhal affections of the mucous membranes Further, the decided alkalinity of the water probably accounts for the favourable results recorded in rheumatism and urinary disorders A recent development has taken place at Ems in the installation of a plant which evaporates the waters in vacuo and produces a powder containing the active salts of the natural waters We have examined a sample of this powder and find that it contains the chief constituents of the natural water, and in the same proportions. Thus, we found it contained 65·52 per cent. of bicarbonate of soda and 30·42 per cent. of sodium chloride. Magnesium and calcium salts, however, which we found present in the bottle of water, were absent in the powder, probably because these naturally separate on concentration. Their presence, however, is probably not important. It is interesting to note that in the powder the sodium salt occurred as a bicarbonate and not as normal carbonate. The water we examined gave a total mineral residue of 2·94 grammes per litre. This contained 1·75 grammes of carbonate of soda, 1·05 grammes of sodium chloride, 0·13 gramme of calcium carbonate, and 0·068 gramme of magnesium carbonate. We also examined some pastilles which are useful for throat medication. These contained the same salts as the natural water. The water is more effective therapeutically when taken warm. The temperature of the waters at the source is from 83° to 135° F. They are probably radio-active.

PNEUMOSAN.

(THE PNEUMOSAN CHEMISCHE FABRIK, 157, GREAT PORTLAND STREET, LONDON, W.)

Pneumosan is described as an amyl-thiotrimethylamine compound. The justification of this title appears to be in the fact that amongst its important constituents are methylene blue, which chemically is tetra-methyl thionine hydrochloride, and valeric acid—the oxidation product of amyl alcohol. A third constituent, according to our analysis, is codeine phosphate. The pharmacology of these three constituents is well known. The combination has been tried as an injection in tuberculosis with results which are reported with a confidence that has attracted attention. Reports have appeared which apparently show that in the early stages of tuberculosis the administration of pneumosan is followed by a marked improvement in the condition of the patient. An abatement of fever is recorded, and rise in the opsonic index is said to take place. Reference is made to the value of the valeric acid in the product as influencing a favourable action over the nervous system. The preparation has been analysed and the results have been communicated to us. Our own examination bears out the statements in regard to the principal constituents. We found, for example, that on evaporation of the dark blue fluid a residue was obtained amounting to 1·70 per cent. This on incineration yielded a mineral residue equal to 0·11 per cent. On distillation valeric acid was obtained in the distillate amounting to 0·765 per cent. The same figure was obtained when pneumosan was extracted with ether, the ether taking out apparently the whole of the valeric acid. Further examination showed the presence of codeine combined with phosphoric acid. We found present codeine 1·427 per cent. and phosphoric acid 0·38 per cent. The physician will be helped in his opinion as to the therapeutic claims made for this preparation by a knowledge of its constituents, and we are glad of the opportunity of bringing this information to his notice. A note on pneumosan as a remedy for tuberculosis appeared in our columns of March 30th, 1912, and further reports have appeared in other publications.

ZYMINE PEPTONISING POWDER.

(FAIRCHILD BROS. AND FOSTER, ALBERT CHAMBERS, 64-65, HOLBORN VIADUCT, LONDON, E.C.)

The enzyme products of this firm are well known. There has recently been issued a smaller-sized package of the zymine peptonising powder which readily effects, amongst other things, the peptonisation of milk. The reduced size adds to the convenience in practical use of this agent. We have tried it in regard to the peptonisation of milk and the digestion of starch, and in both cases the results were satisfactory. It rapidly liquefied starch jelly, and ultimately converted it into sugar.

(1) "TABLOID" LYMPHATIC GLAND; (2) "KEPLER" MALT EXTRACT WITH GLYCEROPHOSPHATES; AND (3) "TABLOID" ADJUSTABLE HEAD DRESSING

(MESSRS. BURROUGHS WELLCOME AND CO., SNOW HILL-BUILDINGS, LONDON, E.C.)

1. The tabloid lymphatic gland supplies a convenient means of administering this organo-therapeutic substance. Treatment with lymphatic gland substance is based upon the view that when tonsillar enlargement occurs it is an attempt on the part of nature to increase the lymphoid tissue of the body. The trials in cases of enlarged tonsils and adenoids in children indicate that the snoring has been improved and the tonsils diminished in size. 2. Kepler malt extract is an excellent vehicle for the glycerophosphates which comprise the salts of calcium, magnesium, potassium and sodium. The extract shows a remarkable digestive activity on farinaceous foods, and we had no difficulty in confirming the presence of the glycerophosphates enumerated. 3. We have already described a tabloid adjustable head dressing the convenience of which threatens to replace the old roller bandage. The dressing is now issued in a large size, and therefore supplies a covering in circumstances where the primary dressings require increased accommodation. The numerous useful applications of this head dressing will easily occur to the surgeon. The dressing is compressed, and so far justifies its description of a tabloid. At any rate, when packed it goes easily into the waistcoat pocket.

MALT EXTRACT WITH HÆMOGLOBIN.

(A. WANDER, LIMITED, 1 AND 3, LEONARD STREET, FINSBURY, LONDON, E.C.)

This is a crystalline preparation comprising the extractives of malt, which include its active digestive principle. It is reinforced with hæmoglobin. We found that on boiling a solution of the preparation a coagulation occurs which carries with it the colouring matter. Viewed with the spectroscope the solution showed the characteristic absorption lines of hæmoglobin. The combination appears to be a useful one in cases where the administration of assimilable iron is indicated. The preparation is palatable and is both a nutrient and hæmatinic.

CYSTOPURIN.

(A. WÜLFING AND CO., 12, CHENIES STREET, LONDON, W.C.)

Cystopurin is a compound of sodium acetate with hexamethylene-tetramine, the latter now being accepted as a useful bactericide for the urinary tract. The presence of sodium acetate is regarded as assisting the action. Sodium acetate, of course, is changed into the carbonate, and so favours an alkaline condition. The sodium salt is also diuretic. Cystopurin was favourably mentioned in a recent communication to our columns on tuberculosis of the urinary tract, by Mr. J. Howell Evans.[1]

THE AYMARD PATENT MILK STERILISER.

(THE AYMARD PATENT MILK STERILIZER COMPANY, LIMITED, ST. MATTHEW'S WORKS, IPSWICH.)

The principle upon which the effective action of this milk steriliser is based is quite simple. The apparatus consists of a container for the milk, beneath which is a boiler generating steam which travels through a jacketed space around the milk chamber. The milk is therefore not in direct contact with the source of heat; burning is avoided and the taste of the milk is not altered. The temperature obtained is, of course, that of steam at the existing atmospheric pressure, the milk chamber acting as a condenser. Following the directions supplied, confidence may be felt that sterilisation is accomplished by this apparatus.

---

THE LANCET.

LONDON: SATURDAY, OCTOBER 11, 1913.

Education and Examination.

WE publish again this week certain selected addresses delivered at the commencement of the October session in the various medical schools, and among those addresses is one by Sir WILLIAM OSLER which, like every public saying of its distinguished author, merits close attention by those interested in the progress of the medical profession. *Sir WILLIAM OSLER, it will be seen, speaks* throughout as a frank critic of examinations; he finds overrated both their importance as a test to those who pass them, and their value as machinery for educational purposes. He does not go so far as some have done and suggest that examinations should be abolished, for he is a practical man, and realises that the public, who depend on our professional ministrations, should have a guarantee, itself open to test, that those on whom they rely for medical service are educated up to a certain standard. Examinations form the ready way in which it is possible for those responsible for the medical education of the country to make out a list of practitioners who can be publicly hall-marked as educated, but to allow this is not to allow that in the multiplicity of examinations lies the safety of the public or the elevation of the medical profession to any exalted academic level. We have before now expressed in these columns our entire approval of a motion introduced at the General Medical Council many years ago by that fine and clear thinker, Mr. T. PRIDGIN TEALE, which ran as follows: "That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student, but damaging to medical education." The figures which Mr. TEALE depended upon in support of this motion indicated that the percentage of rejections at medical examinations had progressively risen from 12·4 in 1861, to 22·2 in 1876, to 34·8 in 1886, and to 41·9 in 1895, while, as Sir WILLIAM OSLER shows in the address which we publish to-day, the five years 1908-12 display a continuation of this significant movement. There can be no two opinions in the matter here—something is wrong when we regard such a percentage of rejections at examinations as the normal outcome of our methods of education.

The statutory period of studentship in medicine in this country is five years, and for practical purposes the time taken by the student to pass his necessary examinations is now seven years. Seven years is a large slab of any man's life, and when those years are taken between such ages as 19 and 26 they cover the flower of adolescence. Stronger in body perhaps, and for certain both richer in learning and more discreet in council, will the young man become, but never again for him can the days have quite the radiancy and flavour of youth. It is no light thing, therefore, that this precious period should in the case of our medical students be too often a period of muddle and mortification. Seven years is not too long a time in which to acquire a working knowledge of the medical profession; but, again, in the absence of any definition as to what constitutes a working knowledge of the medical profession, five years may not be too short a time. It is admitted now on all hands that the medical man must remain a student to the end of his days, and no medical men are happier than those who recognise this fact and who steadily maintain themselves in touch with their profession by attendance at post-graduate classes or by an interchange of views at scientific debates, where personal experiences can be collated and the latest general principles can be adopted with some fulness of knowledge. If the medical man is thus happy in adding to his store of wisdom, why, it may be asked, condole with the medical student because his time spent in adding to his store of wisdom grows longer? The point is that the medical student and the post-graduate student are not in the least comparable persons, while in speaking of the modern medical student we are speaking of a young man for whom it is probable that somewhere in his lengthy career of examinations mortification awaits him. The post-graduate student continues to work, as opportunities serve him, at the practical side of his profession, either in the direction which has for him the chief scientific appeal or that in which he feels that his knowledge particularly requires supplementing. In either case he works *con amore* along lines agreeable to himself, in order to satisfy his conscience, to realise his ideals, and perhaps to make as certain as possible of professional success of a desired sort. The medical student in entering for his first examination may be single-minded in his desire to get forward and to learn more. The rejected student works in no such spirit at all, and a vast number of our students are rejected at least once. In many instances there is with the rejected student an abiding sense of injustice. Of course, we know that very often that sense of injustice is not justified; on the other hand, it must be admitted that the element of chance plays a considerable part in the results of examinations, both pass examinations as well as competitive. In every final examination in medicine we may be fairly certain that some 15 per cent. of the candidates upon re-examination would change their places from rejected to passed, and *vice versâ*. Professor EDGEWORTH'S well-known figures in respect of examinations for the Indian Civil Service, the Home Civil Service, and the Army may be recalled. In these examinations he found in an ingenious manner the element of luck to be such that in any given examination the chances of displacement upon re-examination would amount to one-seventh. Again, there is a feeling, sometimes just and sometimes not, among many students that, although they do not happen to be able to satisfy an examiner with the answer expected, often the question is of the sort that in real life would have had no terrors, inasmuch as in real life either there would be time to clear up the point by consultation of books, or it would not matter in the least whether the point was cleared up.

Students who have grounds for considering that the element of luck is too high, or who feel that an examiner is trying to pose them rather than to ascertain the value of what they know, do not face re-examination with any great relish, and some are beaten before the fight begins.

What is the lesson to be drawn from the admitted fact that our system of examinations, however necessary and however honestly planned, may have a blighting effect upon what is best in the medical education of many of our students, leading too often to a waste of the time of both teacher and taught? Dr. WILLIAM HUNTER, of whose annual report as dean of the Charing Cross Medical School a large portion is published in our present issue, supplies interesting material for an answer, and the answer is coördination. Dr. HUNTER is speaking of London only; and the education of the London medical student is in a critical position, as we await anxiously the new scheme under which the University of London may prove itself a more vital and practical force in the education of our students, making full use of the splendid pathological material of the metropolis and of our unrivalled system of clinical training. But in London there are educated a very large percentage of all English medical students and not a few of those who receive their degrees or diplomas from other educational centres, and if order is introduced into the education of the London medical student we shall have taken a great step towards removing the general conditions of waste and disappointment. What are really necessary at the present moment are patience and adaptability. If with as little friction and delay as possible a new scheme comes into being for the education of the London student possessing the admitted virtues of our present system, but having also a simplicity, economy, and effectiveness which results show to be lacking now, much indeed will have been accomplished. Those who are providing for the country with great zeal and self-sacrifice the national training of our young medical men are not of one mind in detail with regard to a metropolitan university; but as all alike deplore the multiplicity of examinations for which the student has to sit, and the inevitable interference with the smoothness of the curriculum which is caused by the scandalous number of rejections, we believe that differences of opinion, now so acute, may greatly disappear during the work of reconstruction. London should be able to show the way to employ clinical opportunities and pathological resources in the education of the medical student in such a manner as to transform examinations from vexatious and extravagant breakdowns into reasonable halts upon a well-planned journey.

The Rag Flock Act, 1911.

SINCE the measure known as the Rag Flock Act was passed in 1911 experience has shown that unless certain amendments are shortly introduced its salutary intentions may be defeated. The main purpose of the Act was to prevent the use of insanitary material, whether it was made from rags or anything else, in the manufacture of flock for *bedding*. It was an Act primarily designed to secure clean materials for the mattress on which we sleep, and no one is found to say that this is not an important matter. Judging from the attitude of some magistrates, however, there seems to be a disposition on their part to treat offences under the Act in a trivial way, and this is not in accord with the best traditions. Such an attitude may arise from an ignorance of the real importance of the aim of the Act or because the Act allows a freedom of construction which enables clear cases of offence to escape. It appears, according to the views of at any rate one sanitary authority—viz., the health committee of the corporation of Bradford—that the Act requires strengthening in regard to working definitions. The members of this committee have made, it seems to us, some trenchant suggestions in this direction. They have asked, for example, for a definition of the expression in the Act "flock manufactured from rags" so that it may include flocks whether made directly or indirectly from rags or from some one or more intermediate processes in the conversion of rags into shoddy cloth, as well as flocks developed in the milling, raising, cropping, and other processes which take place after shoddy cloth has been woven. They suggest, also, that the word "rags" shall include all fabrics whatsoever, whether woven or felted, which are admittedly destined for conversion into flock. These recommendations to the Local Government Board, made with the view of securing an amendment of the Act mean that there are deficiencies in the measure which permit a limited application of its provisions, or which lead to a failure to secure a conviction when an obvious breach of sanitary requirements has been committed.

We learn also that quite recently a practice has arisen which, while satisfying the Act in regard to the statutory limit of chlorine capable of being washed out of rags, may leave in the material undesirable solids and dirt. It may be remembered that the Act states that flock may be passed as having been satisfactorily cleaned or washed which does not yield to distilled water more than 10 milligrammes of chlorine in one litre of wash prepared on well-regulated lines. This test is based, of course, upon the probable presence of soluble impurities in the fabric, but leaves untouched the question of insoluble impurities. The Act would seem, in short, to provide for soaking the material, but not for the thorough washing of it, using that word in the sense of removing all impurities detachable by a washable process. It follows that a mere soaking of flock may fulfil the requirements of the Act in regard, that is, to the chlorine standard (soluble impurities), but the process still leaves the fabric unclean, dirt of all kinds and much objectionable matter not being eliminated by the ordinary process of soaking. The matter is simple in the case of linen. It is obvious that the mere soaking of a shirt in water will not render it clean or presentable, thorough washing is required to take away all evidence of soiling. That is what the Rag Flock Act should ensure in the case of rags intended for bedding if it is to succeed at all under the dignified title of a sanitary reform. On the face of it, it is difficult to suggest how the question of mechanical scouring, the removal of dirt and so forth, can be controlled by laying down a standard unless that control be an actual experimental washing itself. Possibly it may be practicable to add to the efficiency of the test by requiring, in addition to a limited yield of chlorine a minimum of colouring material or of attached impurities which are capable of being removed by the ordinary process of washing. The wash water could be examined both for chlorine and suspended impurities, and a minimum allowance imposed in the latter case as well as in the former. It is quite clear that if an efficient washing process has been conducted by the rag flock manufacturer he will have nothing to fear when such a test is carried out upon his material, for thorough washing would exhaust it of those very impurities which the sanitary officer would look for when an examination is made. The whole matter is of the first importance, and we beg to call the attention of all sanitary authorities to the existing situation.

Annotations.

"Ne quid nimis."

RELIGION AND SCIENCE.

UNDER the presidency of the Bishop of Winchester the fifty third annual Church Congress was held last week at Southampton. The programme challenged criticism by its boldness and novelty. Old questions were set aside and attention was centred upon the work of the Church in the life of to-day, faced as it is with the changes which must inevitably arise in days of progress and development. The deliberations, which were imbued with modern spirit, were concerned with such urgent social questions as the women's movement in its larger aspect, rural betterment, the ethics of property, and (as was appropriate in Southampton, a large port of exit to the great world) the difficult problem of the relation between civilised and backward races. The majority of the speeches on the position of woman indicated the opinion that her first duty was the maintenance and perpetuation of life, that a larger share in social service should be given to her, and that there should be increasing coöperation in public affairs which fall peculiarly within her influence between men and women; little direct allusion was made to the question of female suffrage. The problem of the races, which means much to Great Britain, the world's first colonising force, was discussed from many standpoints. The note of the Congress was that the advances of anthropological science would assist in the foundation of fruitful and successful government. It was felt that the control of backward races by a civilised Power must be "full, complete, and exercised in the light of day," and that although it seemed unwise to force education on people who did not want it, yet all nations and individuals should be given every opportunity for development. The Congress was in many respects a distinctive one and full of hope. It is too early to estimate its real value. But it has done much to establish high ideals, to help forward the cause of social progress and reform, and to forge new and closer [illegible] the Church and the affairs of our collective [illegible] ess as at the recent meeting of [illegible] ame obvious that the antagonism between religion and science is practically in abeyance. Science is, as Sir Oliver Lodge said in his stimulating Presidential Address to the British Association, an affair of the [illegible] intellect— [illegible] and that [illegible] much tried by the vast processes of examination that it now has to carry on, and the faculty of imagination is increasingly employed in these processes. As a consequence a healthy position has been reached in which the faith of the religious man can be respected by earnest scientific workers, while the huge undertakings of science can be supported by religious believers, who see in the stupendous facts revealed to them no contradiction to their beliefs and hopes.

SEPTEMBER AT HOME AND ABROAD.

UNLIKE August, which was cool for the time of year over the greater part of this country, September's temperature was at least equal to the normal, and over a large portion of the kingdom a little above it. In the matter of sunshine, too, it was relatively more generous than the preceding month, although it still fell somewhat short of the average, and was dull when compared with some of the brightest of past Septembers. Like both July and August, its rainfall was below the average in most localities, but not in such a marked degree. In the metropolitan area, as represented by Kew, the mean maximum temperature was 66°, or rather more than a degree above the average, while the mean minimum was 50°, also a trifle more than a degree above. The warmest and brightest weather came during the last week, when, under the influence of a wind current from the south, the sheltered thermometer rose to 70° or above on five days and only descended to about 55° at night. The first week was the most sunless ever recorded in September, and its remarkable dulness has been seldom surpassed even in the months November–January. At Kew the first seven days gave a total sunshine of only 8.6 hours, and at Bath 8.3 hours, but when the dense canopy of cloud had once been broken it never formed again for more than a day, and most of the remainder of the month was fairly bright. The aggregate number of hours at Kew was 127, against an average of 141. As many as 51 hours of the 127 were recorded during the last seven days. Rain fell on 12 days, and yielded a total of 1.73 in., a figure nearly a quarter of an inch below the average. At Bath the mean temperature was slightly higher both during the day and night than at Kew, while the sunshine was practically the same. The rainfall, on the contrary, was much heavier, owing chiefly to a sharp thunderstorm on the 5th. The aggregate figure was as high as 3.17 in., or 0.95 in. above the normal. Further north the mean temperature decreased. At Nottingham the mean maximum and minimum values were 65° and 48.5°, at Harrogate 62° and 49°, and at Buxton 60.5° and 46.6°. Both at Nottingham and Harrogate the total sunshine was about ten hours less than at Kew and Bath, but at Buxton it was about 20 hours less. At Buxton, although rain fell on no less than 18 days, the total fall was no more than 1.83 in., or 2.34 in. below the normal. On the south coast of England the mean maximum temperature differed little from that in London, but the mean minimum was appreciably higher. At Brighton the mean night was nearly 4° warmer than at Kew, and at Bournemouth 2° warmer. The weather was also much more sunny; at Brighton the total sunshine was more than an hour a day above that at Kew. The extreme south west of England had rather cooler days and milder nights than the rest of southern England and also more rain and less sunshine, but at Jersey the month was warmer, brighter, and drier than on any part of the main land of this country. The mean maximum temperature equalled 68° and the mean minimum 55°, while the sun shone during 191 hours, exceeding the average by five hours, and rain fell on only nine days, yielding the small total of 0.65 in. The Continental weather was normally hot and dry in Southern Europe, the temperature rising to between 80° and 90° in Italy and the Spanish Peninsula during the earlier half of the month, and subsequently to between 70° and 80°. In France the heat was not, as a rule, very great, and the general condition rather variable, with spells of showery, thundery weather, while in the central countries, where the greater part of the period was dry, the decrease in warmth during the latter half was very noticeable. At Paris the mean maximum temperature was 69°, or 3° higher than in London, and at Brussels 68°, but at Berlin it was only 65°. The mean minimum of the nights was nearly the same in all three capitals, being 49° at Brussels and 51° at Berlin and Paris. At Berlin there were only seven days with rain, and the total was no more than 1·66 in., and at Brussels eight days, with a total of 1·49 in. Paris, however, was rather less dry, rain falling on ten days, and giving an aggregate of 1·78 in. Paris was, relatively, more sunny than during August, a total number of hours equal to a little more than six hours daily being registered. In London the figure was little more than four hours daily. The greatest shade heat at Paris was 78° on the 3rd, a figure that was equalled in some parts of London towards the end of the month, but in the French capital the thermometer reached or rose beyond 70° on as many as 14 days. Brussels also had a temperature of 70° or above on 14 days, but at Berlin there were only five readings as high, as in London (Kew). The deluge that accompanied the thunderstorms in the extreme south of France on the 29th was comparatively local, but was extraordinary for the tremendous quantity of water falling in a short time. Over many thousands of acres the amount appears to have varied between 4 in. and 7 in., all of which fell within 24 hours.

THE ETIOLOGY OF RELAPSE IN MALARIAL INFECTIONS.

IT has been asserted by certain experts quite recently that while our knowledge of the malarial parasite, its morphology, mode of transmission, treatment, and prophylaxis is fairly complete, the etiology of relapse in this malady has not yet been satisfactorily determined. This is the more to be regretted since there are good grounds for believing that relapses in malaria lead often to more serious consequences than do primary attacks. The Department of Sanitation of the Isthmian Canal Commission began two years ago an inquiry into the various predisposing causes of relapse in malaria, with the object of verifying or excluding the several hypotheses at present current concerning the etiology of relapse, as well as to ascertain the best methods of prophylaxis and treatment against it. The material thus collected has not yet been fully dealt with, but meanwhile Dr. W. M James, physician to the Ancon Hospital, has discussed in the *Journal of Infectious Diseases* the various hypotheses put forward. His article is entitled "Notes on the Etiology of Relapse in Malarial Infections," and in it he directs attention more particularly to the two principal hypotheses advanced on this subject, both of them having one factor in common—namely, that relapse is due to the renewal of the asexual cycle of the malarial parasite to a degree when clinical symptoms become observable, and a resistance of the latent parasites, whatever may be their form, to quinine. In summarising his views, Dr. James says that if the hypothesis be accepted that the asexual cycle alone is the cause of relapse, and that under certain conditions there is established a relative immunity against quinine, an explanation is afforded of all the facts associated with the etiology of this condition. Relapse, he goes on to say, is one of the most common factors in malarial infection, and the asexual cycle is that phase of the parasites found to be most frequently connected with the primary infection and relapse. Relapse follows often upon the so-called spontaneous cure of malaria because the asexual cycle in such instances often persists in numbers which can be detected by the thick-film method. Infections treated insufficiently with small doses of quinine will in all probability relapse, because the parasites of the asexual cycle in the spleen and marrow are very slightly, if at all, affected thereby. On the other hand, relapse is less likely to occur when the infection is promptly and vigorously treated, for the older the asexual cycle the more resistant to quinine does it become. When a relapse occurs with manifestation of parasites in the peripheral blood during the administration of quinine by the mouth in sufficient doses, it is evident that there must be faulty absorption of the drug, and that the method of medication ought to be altered. The potential of vitality of the asexual generation is not unlimited, and owing to this, if death does not supervene in the course of a malarial infection, the infection itself will in time die out, but often not until it has done irreparable injury to the patient. It is easier to eradicate an infection in persons who are otherwise in good health, because in these cases the natural protective forces of the body aid the action of quinine. In Dr. James's opinion, the practical importance of the above hypothesis lies in the value it has as a guide to the treatment of malaria. Small doses of quinine even in the mildest infections serve only to render the asexual cycle relatively immune, so that larger doses, which if they had been given early in the attack might have exterminated the parasites, are at a later stage without effect. After numerous experiments with varying doses of quinine Dr. James, in conjunction with his colleague, Dr. W. E. Deeks, of the Ancon Hospital, came to the conclusion that the best method of treating malaria by quinine is to give 45 grains of the sulphate daily, dividing it into three doses, each of 15 grains. By this mode, it is contended, recurrent malaria has been practically banished from among the Americans in the Panama Canal Zone, and to a large extent among the European labourers employed on the Isthmus. But it has to be remembered that the latter are also heavily infected by syphilis, a complication which lessens the efficacy of the routine treatment of malaria until the syphilis itself has been successfully dealt with.

THE NATIONAL GAS CONGRESS AND EXHIBITION.

THERE is an extremely interesting collection of modern gas appliances on view at the National Gas Exhibition at the International Exhibition Halls, Shepherd's Bush, London, which was opened on Oct. 1st by the Lord Mayor of London in the presence of a large gathering of scientific, industrial, and municipal authorities The exhibition remains open until Nov. 1st. The occasion commemorates the jubilee of the Institution of Gas Engineers and the centenary of public gas-supply. The exhibition reflects the enormous progress that has been made in the methods of gas manufacture and in the appliances employed for utilising gas for power, lighting, and heating purposes. The demonstrations are of an instructive and practical character. An excellent series of popular lectures has been organised which is intended to familiarise the public with the proper and economical use of gas in domestic service. We note with special interest that many of the advances demonstrated give evidence of a regard for hygienic considerations, and this is particularly so in respect of gas stoves. The models now made by the leading gas firms excite our admiration for the excellence of their design, the economy with which they deal with gas as a fuel, and the methods adopted to secure comfortable and healthy warmth for domestic purposes. There is also an incidental display of the numberless by-products obtained in gas manufacture, including ammonia compounds, synthetics, dyes, antiseptics, and so forth. It is interesting to note that medical science owes much of its impetus to the gas industry. The gas industry supplied, for example, the early antiseptic workers with antiseptics, it furnished also a series of valuable antipyretics and anodynes, while bacteriology owes much of its advance to the aniline dyes which served to bring the organisms of disease into view and into differentiation. The exhibition, therefore, has many points of interest to medical men apart from the great public matters of efficient and healthy lighting and heating.

PERITONSILLAR ABSCESS EXTENDING DOWNWARDS AS FAR AS THE SECOND RING OF THE TRACHEA.

IN the *Boston Medical and Surgical Journal* of August 21st Dr. G. L. Richards has reported a case in which suppuration beginning in a peritonsillar abscess extended downwards as far as the second ring of the trachea. The patient was a well-nourished man, aged 42 years, who had enjoyed good health except for occasional attacks of quinsy. He went to hospital with a history of sore-throat for several days followed by difficulty in breathing and swelling of the entire left side of the face and neck. The left tonsil had been lanced on the previous day and again on the morning of admission but without relief, and the abscess had been enlarging. He was breathing with great difficulty, and there were occasional paroxysms of dyspnœa and coughing. The entire left side of the neck down to the clavicle was swollen and œdematous. Examination of the throat, which was done with difficulty, showed that the tonsil, lateral wall, and the supratonsillar area were intensely swollen. The pulse was 124 and the patient was nearly cyanotic. The skin of the neck was very tense, but no definite fluctuation could be felt. A large peritonsillar abscess was diagnosed. He was seated in a chair, the tongue was depressed, and an incision was made in the supratonsillar fossa. This caused a discharge of pus and a paroxysm of coughing. As this incision was made rather for diagnosis, it was small. An attempt was made to enlarge the opening. A gush of pus escaped, and at the same moment an inspiratory spasm, a cry, and cessation of breathing occurred. He was immediately placed on the operating-table. Unfortunately, no preparations had been made for tracheotomy, and in lifting the patient on to the table the knife was dropped on the floor and lost for the moment. A hurried call for a knife caused the assistant to bring a thin nasal chisel by mistake, and several seconds were lost before a knife was obtained. The head was placed somewhat over the edge of the table, the neck was put on the stretch, and an incision was made at the supposed site of the trachea. Much to his surprise, Dr. Richards entered, not the trachea, but an abscess. The abscess had burrowed downwards to a little below the second ring of the trachea, producing phlegmonous inflammation of the tissues of the neck, and had pushed the trachea well over to the right While the pus was still flowing the trachea was found and quickly opened. The patient was apparently lifeless, but the pulse was still beating. Artificial respiration was performed, and after a few seconds natural respiration began and a tracheotomy tube was inserted. The peritonsillar abscess and the abscess near the trachea were then widely opened with the aid of the finger. The two were found to communicate. The patient was kept in bed with his feet about a foot higher than his head for the next three or four days, a wick being inserted around the tracheotomy tube. The temperature, which was 101·5° F. on admission, slowly fell. An abundant discharge of pus took place from the mouth and at the side of the tracheotomy tube for a few days The tracheotomy tube was removed on the eighth day, and the patient was discharged from the hospital cured on the seventeenth day. The case illustrates the danger of allowing a peritonsillar abscess to develop. The pus probably forced its way through the fibres of the superior constrictor of the pharynx, which is in contact with the tonsil, and gained access to the prevertebral fascia. Following this fascia down the neck it came in contact with the larynx and trachea. It was an error to attempt to open such an extensive abscess without being prepared for tracheotomy.

HARD WATER AND OLD AGE.

A FEW months ago we received a communication from a lay correspondent in which he expressed his belief "that the lime in common water has much to do with bringing on old age." In an annotation entitled "Hard Water Fallacies," which appeared in our issue of June 28th, we said that the belief, although fairly common, was fatuous, pointing out that the amount of lime salts consumed in the daily diet was largely in excess of that contained in a daily allowance of the hardest water supplied to the community. In an interesting article published in another column of our present issue under the title of "Hard *versus* Soft Water," Dr. J. C. Thresh gives the results of an extended inquiry which he has made into the question of a possible relation between the hardness of water and the death-rates. His conclusion is that there is no such relation. Taking the averages for the five years (the period of his calculations) the differences between the death-rate for the area with the softest waters and the area for hardest waters is, he points out, in one instance (the metropolitan area) only 0 1 per 1000, and in the other (country towns) only 0 2 per 1000, whilst the moderately hard water areas taken together have a death-rate exceeding that of the hard water areas of from 0·1 to 0 2 per 1000. These differences he regards as so slight that only one conclusion can be deduced—namely, that the natural character of the water-supplies in this country has no effect upon the death-rates. Incidentally they confirm also a previous opinion which he expressed, that the filtered water from the sewage-polluted rivers, the Thames and Lea, is as wholesome as the water from our very deep wells and gravel springs. In 1893 the famous River Pollution Commission reported that "where the chief sanitary conditions prevail with tolerable uniformity, the rate of mortality is practically uninfluenced by the softness or hardness of the water supplied to different towns, and the average of mortality in the different water divisions varies far less than the actual mortality in the different towns of the same division." There is obviously a concordance of observations here which should place at rest the contention that an increased rate of mortality is favoured by hard water. It may be added, however, that a hard water-supply introduces enormous economic inconveniences, amongst which are the furring of the service pipes and fittings and a wastage of soap.

THE TYPE OF BACILLUS IN TUBERCULOSIS OF THE BONES AND JOINTS.

THE view that tuberculosis of the bones and joints is almost exclusively due to the human type of tubercle bacillus is emphasised in the *Deutsche Medizinische Wochenschrift* for Sept. 18th by Dr. B. Möllers, Koch's late assistant. His investigations in 12 cases of tuberculosis involving the bones and joints failed to demonstrate any but the human type of tubercle bacillus. Of the patients examined, three were between the ages of 5 and 16, the rest being older. Pure cultures of the bacilli were obtained in every case; in one case three cultures were obtained at different periods, and in another case two cultures. From the 15 cultures thus obtained 49 rabbits were inoculated with a dose of 10 mgm. each. These subcutaneous inoculations, which were to a certain extent supervised by Koch, conclusively proved, according to Dr. Möllers, that only the human type of tubercle bacillus was present. He has also collect [illegible] on this subject made by 15 workers in 163 [illegible] 12 cases already referred to) of tuberculosis of the bones and joints. Of these, only four were associated with the bovine type of bacillus. The remainder were undoubtedly due to the human type. In other words, only 2 45 per cent. of these cases showed the bovine type of bacillus. These conclusions are much at variance with those to which Dr. J. Fraser has been led by his recent examination of 70 cases of tuberculosis of the bones and joints. He found the human type of bacillus in 26 cases and the bovine type in 41, the remaining 3 showing a mixture of the two types. If Dr. Fraser's and the other workers' observations be compared with reference to the ages of the patients, it is seen that in children under 5 years Dr. Fraser finds the human type of bacillus in 27·27 per cent., and the bovine type in 72·72 per cent., while the other workers find the human type in 100 per cent. Between the ages 5 and 16 Dr. Fraser's figures show the human type in 55 per cent. and the bovine type in 45 per cent., while the other workers' figures show the human type in 94 54 per cent and the bovine type in 5·45 per cent. In adults over 16 Dr. Fraser has not found the bovine type once, while the other workers have found it in 2·2 per cent. Dr. Möllers argues that these differences cannot wholly be explained by the facts that all but three of Dr. Fraser's patients were under the age of 12, and that his material was gathered from a small area comprising Edinburgh and its immediate neighbourhood. He suggests that Dr. Fraser's conclusions should be accepted with reserve so long as the premises on which they are founded are not fully published.

INDUSTRIAL ANTHRAX IN LIVERPOOL.

IN an instructive paper read last year at the International Congress of Hygiene and Demography, and now reprinted, Dr. E. W. Hope and Dr. W. Hanna drew attention to the occurrence of anthrax in Liverpool among a population which does not come under the special provisions of the Factory Act in regard to that disease. These are principally the carters engaged at the docks and quays, who handle imported wool and hides, and the sorters in wool warehouses or skin stores. The Liverpool public health authorities have, in view of its occurrence in this way, declared anthrax to be a notifiable disease. In a period of about eight years 60 cases have arisen in connexion with the importation of these animal products. The majority appear to have been infected in the unloading or carting of hides, either loose or in bales, but 13 were engaged in handling or sorting wools, such as sheep's wool or goats' hair in wool warehouses, while 7 were infected from horsehair or bristles in hair factories. In the latter case the hair was derived from Russian sources; in the case of the hides infection seems to have been brought from all parts of the world, but chiefly from China and the East Indies. The site of invasion in the case of the dock labourers and carters was usually the cheek, but in some instances it appeared elsewhere as a result of the existence of a skin abrasion which became inoculated. The disease in persons of this class is apt to be specially severe, as, unlike the factory workers, they are not familiar with the existence of any risk from anthrax and do not recognise its early signs. The writers do not consider that the danger of anthrax from foreign imported animal products was diminished, but they find that the number of cases in Liverpool shows some tendency to diminish, which may be ascribed to greater care in handling material and to the efforts of the health department to bring to notice the various methods of prevention, short of disinfection, which should be adopted. Protective gauntlets have been provided by shipping firms in many cases, but the difficulty of getting the men to wear them is very great. But much is done by means of cautionary [illegible] the carrying of hides on the men's [illegible] mechanical means of removal, and like measures. In recent years the ear[illegible]e pustules and prompt treatment in [illegible] and [illegible] Sclavo's serum have materially diminished [illegible] cases.

AUTUMN COURSE OF DEMONSTRATIONS AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

INSTEAD of appointing special guides for visitors to the Museum the Council of the Royal College of Surgeons of England some years ago resolved to institute a series of demonstrations to be given by officers on the Museum staff. During the past five years these demonstrations have been well attended, although the aim of the demonstrators has been to appeal to the research student rather than to the candidates for ordinary examinations in surgery. The present course of demonstrations, which commences on Friday, Oct. 17th, at 5 o'clock, will consist of eight demonstrations, three being given by the conservator, Professor Keith, three by the pathological curator, Mr. Shattock, and two by the odontological curator, Mr. Colyer. The dates and subjects of the demonstrations will be duly noted in our "Diary of the Week." One of the most interesting of the series should be that given by Professor Keith on Oct. 17th, when a peculiar form of defective bone growth—described a few years ago by Porak and Durante, under the name of *Dystrophie periostale*—will be described and discussed. Two complete examples of this curious and instructive condition have been recently added to the Museum. The demonstrations are open free to all medical men and medical students, and cover subjects which are included in higher examinations in surgery.

REINFECTION AND SUPERINFECTION OF PRIMARY SYPHILIS.

THE discovery of the specific parasite, the study of experimental infection in animals, the application of an exact method of diagnosis, and the introduction of a new therapeutic agent are four important factors which have contributed toward revolutionising our old notions of many obscure problems of syphilography. There are two fundamental problems in the question of syphilitic immunity: (1) whether the immunity period coincides, or not, with that of the disease—that is to say, if the subject can be said to be immune only to such an extent, and so long as he is ill, or if, on the contrary, the state of resistance to infection lasts, and if so how long, after cure has taken place—i.e., after the extinction of all the specific parasites in any situation and under any form; (2) whether the immunity period is capable of *extension*—if, that is, to say, it must be interpreted as a condition of absolute resistance of the whole organism, or if, on the other hand, a partial resistance must be admitted as against a receptivity of some parts of the organism. Dr. M. Giuseppe has taken up the study of these problems, giving in a recent number of *Il Policlinico*[1] notes of four cases and a critical investigation of the cases of other observers. Such cases fall into two groups, one in which the clinical picture is made up of the complete development of two cycles of specific infection, while the other comprises cases in which one of these two cycles is incomplete and is therefore represented only by a form of primary infection without secondary manifestations. A study of these cases seems to

show that there ex [illegible]
up by transitional [illegible]
especially by [illegible] 60
possible as a rule [illegible]
neo-infection and pseudo primary forms, it is impossible to distinguish accurately between reinfection and super-infection. Two essential and common facts stood out prominently in all the cases examined by the author—first, the intense and typical lymphatic and glandular regional reaction corresponding to manifestations of primary type; and secondly, the delicacy and precision with which the degree of deviation of the complement signalised modifications of the state of the patients' blood [illegible] with the disappearance or development of [illegible] forms.

FRACTURE OF THE LIP OF THE ACETABULUM.

IN the *Journal de Médecine de Bordeaux* M. J. Guyot has reported a case of one of those minor fractures which have received little attention because they could not be diagnosed before the introduction of radiography. A labourer, aged 41 years, was emptying a pit containing manure when he was surprised by a falling in of the earth and sustained a severe contusion over the left hip. He was thrown down and wounded in the scrotum by the handle of the shovel with which he was working. The wound was sutured by a practitioner and the patient was taken to hospital, where it was dressed, but he was not detained. Abundant suppuration followed, and healing was not completed for 48 days. After the accident he complained of pains shooting from the root of the penis to the left hip and sacro iliac joints. On examination it was observed that he walked with short steps. When he tried to walk more quickly he was prevented by pain in the hip. There was no deformity or vicious attitude of the limb. Pain was especially felt when he walked with long steps or endeavoured to separate his thighs, even when sitting. The only movement that was limited was rotation outwards of the thigh, which was painful. On movement articular crackling was observed, but this was found in other joints, especially the right hip and both knee-joints. A radiogram clearly showed that a fragment of the lip of the left acetabulum at the upper part had been broken off. There was a region of greater transparency in the neighbourhood, which suggested the existence of some osteitis. The outline of the femoral head and of the cotyloid cavity were very clear, as clear as on the opposite side. The patient was examined by an expert and pronounced to be suffering from a permanent incapacity which was estimated at 25 per cent. A fracture of this kind separating a fragment of the acetabulum is rare, and can be discovered only by systematic radiography.

PUBLIC RESPONSIBILITY TOWARDS PUBLIC SERVICE.

THE value of patient, persistent, and probably unobtrusive work in the library as well as in the laboratory still fails of proper recognition at the hands of those in this practical age who constantly use its results without recognising their dependence thereon. Such work supplies the motive power without which the engineer of progress would be unable to propel his vehicle. It is his control and effective direction, it is true, that produce useful work, but the necessary power he must have, and that power *is knowledge gained* by patient investigation in the laboratory, and research in the library. At the recent meeting of the British Association Principal E. H. Griffiths, in his presidential address in the Section on Education, urged the importance of making evident, to the [illegible] instanced the dependence of refrigerating processes on investigations of Joule and Thomson, of the electric[illegible] mear on the researches of Faraday, of the telegraphist on those of Volta and Wheatstone, of the [illegible] of N [illegible] mea [illegible] investigation; and the discoveries of Davy, of Pasteur, of Röntgen, and of Lister, as enabling them to enjoy in security, comfort, and health the fruits of their labours. And so it is also with library [illegible] will be found a review of the [illegible] The resc[illegible] reviewer points out, are of the greatest value for their bearing on public health questions, and should consequently be of interest to municipal bodies and sanitary authorities. It is, therefore, a matter of regret that the subscriptions in support of this most valuable work fall short of the expenditure by £112, which deficit the honorary director, Dr. H. R. Mill, has himself to meet. We feel sure it cannot be necessary to do more than call the attention of the numerous sanitary authorities throughout the kingdom to this fact. A very small individual effort on the part of each of them would remedy this injustice.

THE demonstration by Dr. Hideyo Noguchi, of the Rockefeller Institute for Medical Research, will take place at the Royal Society of Medicine on Monday next, Oct. 13th, at 5.30 P.M. The following will be shown: 1. Pure cultures of various spirochætæ (Treponema pallidum, T. pertenue, T. microdentium, T. macrodentium, T. mucosum, T. calligyrum, and T. refringens). 2. Transmission of syphilis to animals by means of pure cultures of Treponema pallidum. 3. Demonstration of Treponema pallidum in the brain of general paralytics. 4. Transmission of Treponema pallidum from the brain of general paralytics to the rabbit. 5. Production of symptoms and lesions resembling general paralysis in the rabbit by means of an intracerebral or subdural inoculation with Treponema pallidum. 6. Cultural studies of the virus of rabies. These will be demonstrated by the lantern slides and the real objects. Announcements have been made in the lay press for some days of certain discoveries upon which these demonstrations will bear. Dr. Noguchi, as related by our Paris correspondent a fortnight ago, has already given his important demonstration to the Institut Pasteur.

WE have been asked to state that copies of the catalogue of the Museum of the International Congress of Medicine may be obtained from the honorary secretary of the Museum Committee (Mr. H. W. Armit, Ravenhurst, Talbot-road, Wembley), on the payment of the postage (4*d.* per copy).

THE annual dinner of the London School of Tropical Medicine will be held at Prince's Restaurant on Friday, Oct. 24th, under the presidency of Dr. F. M. Sandwith.

GUY'S HOSPITAL MEDICAL AND DENTAL SCHOOLS.—[illegible] and prizes have been aw[illegible] university students (£[illegible] College, Oxford. [illegible] Eric Clark Hinde. [illegible] (£60): Frederick [illegible]ington. Entrance [illegible] (£100): Eric Roland Webb, Dean Close [illegible] Gordon Frank Peters. Certi[illegible]en, Oratory School, Edgbaston. Open Scholarship in Dental Mechanics (£20): Hugh Muir Smith. Scholarship in Dental Mechanics for pupils of Guy's Hospital (£20): George Dee.

HOSPITAL DINNERS.

St. Bartholomew's Hospital.—The annual old students' dinner, which marks the opening of the winter session, was held in the great hall of the hospital on Oct. 1st, under the chairmanship of Dr. Howard H. Tooth, C.M.G., physician to the hospital. Among the large company were Sir Dyce Duckworth, Sir Clifford Allbutt, Professor Howard Marsh, Sir Lauder Brunton, Sir Francis Champneys, Dr. Samuel West, Dr. J. A. Ormerod, and many of the present visiting staff, together with the headmasters of Haileybury, Wellington, and Westminster. The chairman, in proposing the toast of "Prosperity to the Hospital and Medical School," gave a short review of the past year's work, which he said had been one of activity in all departments. The teaching had become more and more organised, and specialists had now been appointed to take charge of each of the special departments, while the systematic lectures had disappeared. The petition for a charter of incorporation of the medical school had been presented early in the year. Referring to the report of the Royal Commission on University Education in London, Dr. Tooth said that these proposals would touch the hospital and medical school at many points and were engaging the earnest attention of the staff. True clinical teaching in England, which brought the student into personal contact with the patient, was the best in the world, and he hoped that that part of our English teaching would be treasured. The effect of the Insurance Act had been to reduce greatly the work of the out-patient and casualty departments, especially on the male side, but there was no evidence of much diminution among the in-patients. The toast was responded to by Mr. G. Acton Davis, acting treasurer of the hospital, who said that during the past year they had had to deal with many difficult problems of administration and finance. Both speakers made feeling references to the premature death of Mr. R. B. Etherington-Smith, and it was announced that the fund to his memory now exceeded £1700. The toast of "The Visitors" was proposed in an admirable speech by Dr. W. P. Herringham, Vice-Chancellor of the University of London, who referred to his aspiration that London University should become to its graduates what Oxford and Cambridge were to theirs, and spoke in praise of the English educational method and tradition. Sir C. Pardey Lukis, Director-General of the Indian Medical Service, and the Rev. Dr. Gow, headmaster of Westminster, responded. Dr. Gow said that he had followed with great interest the controversy on methods of medical education, and he was convinced of the value and importance of the knowledge gained from personal contact between teacher and student and from the *obiter dicta* of the teacher. The health of the chairman was proposed by Sir Anthony A. Bowlby, who spoke in warm terms of Dr. Tooth's personal qualities and of his services to the Officers' Training Corps. The toast was enthusiastically received, and after the chairman had briefly replied an adjournment was made to the library, where a most successful evening was brought to a close.

Guy's Hospital.—The opening of the school year was marked by a dinner in the College dining hall on Oct. 1st, at which the President of the hospital, Mr. Cosmo Bonsor, presided. Among others, the following gentlemen were present: Dr. W. Hale White, Sir W. Arbuthnot Lane, Dr. H. C. Cameron, Dr. Newton Pitt, Sir George Savage, Mr. R. Clement Lucas, Mr. C. J. Symonds, Sir Alfred Fripp, Dr. J. Fawcett, Dr. Herbert French, Mr. R. Wynne Rouw, Mr. Montagu F. Hopson, and Mr. J. Lewin Payne. After the usual loyal toasts the chairman invited the Dean, Dr. Cameron, to present the annual report of the Medical and Dental Schools. In doing so the Dean referred to the extraordinary activity which had been displayed in every department of the medical school throughout the year. Not only had the new pathological department been brought into smooth working order, but the opening of the session was marked by the simultaneous birth of three new departments, those of pharmacology, morbid histology, and chemical pathology, under the direction of Dr. A. J. Clark, Dr. G. W. Nicholson, and Mr. J. H. Ryffel, respectively—departments which were adequately housed, equipped, and staffed. With regard to the future of the medical school, while it would be folly to deny that the present time was a critical one for all medical schools in London, he was able to say this much: that while not a few other schools had sensibly declined, the medical school of Guy's Hospital had at least held its own and even increased its numbers during the past year; and that so far as the financial position of the school was concerned, thanks to the generosity of the governors and other friends, no single scheme for improvement which had won general approval had had to be withdrawn or even postponed for lack of funds. They had set themselves to develop and perfect, so far as possible, the peculiar system of clinical training which was the pride of all the schools of medicine in London, and he thought that the report of the past year's work showed that in this they had been eminently successful. Whatever changes the future had in store for them they had at least been successful in the work which immediately lay to their hand. Mr. Bonsor, in proposing "The Prosperity and Health of the Medical and Dental Schools," spoke of the recent extension of the medical school and the completeness of its equipment both for teaching and research, and said that during all the years in which he had presided over the meetings of the school the one thing which had struck him most had been the absolute determination of the governors and staff alike that no reason whatever should be allowed to stand in the way of securing efficiency in teaching and opportunity for investigation and research, and that no financial sacrifice to attain these ends could be too great. Dr. Hale White, who replied on behalf of the schools, spoke of the enormous debt of gratitude they owed to the long line of treasurers of Guy's Hospital, and especially to Mr. Bonsor, their chairman that evening. Undertaking office at the time of depression both in the hospital and school, he had guided their fortunes to the present unrivalled position. The service of Mr. Bonsor to the schools could never be over-estimated. The work which he had initiated was being admirably carried on by his successor in the office of treasurer, Viscount Goschen, who, to everyone's regret, was unable to be present that evening.

St. George's Hospital.—The annual dinner of the past and present students of St. George's Hospital was held on the evening of Wednesday, Oct. 1st, at Prince's Restaurant, London, Mr. W. Adams Frost, consulting ophthalmic surgeon to the hospital, being in the chair. Sir William Osler, who had delivered the introductory address earlier in the day, which is published in another column of this issue of The Lancet, was the guest of the evening. After the loyal toasts had been drunk, Mr. Frost in an interesting speech reviewed the circumstances which have led to the impending migration of St. George's Hospital from the site which it has occupied now for 180 years, and reminded his hearers of the interesting fact that amalgamation with the Westminster Hospital would mean the reunion of two long-divided bodies. Mr. West, the treasurer of the hospital, and Dr. R. S. Trevor, dean of the Hospital Medical School, replied, and the latter made a fighting speech on the position of the school, alluding to the brave front which it had presented in the face of many adverse circumstances which were alike unanticipated and uncontrollable. The aim of the school had always been, as Dr. Trevor maintained it should be, to turn out practical physicians and surgeons, adding that "if God made man, the Devil made the bookworm." Dr. Rolleston proposed Sir William Osler as "The Orator of the Day" in a happy speech, in the course of which he read out some of the questions from the famous examination paper on the "System of Medicine" which appeared in 1902 in the pages of *St. Thomas's Hospital Gazette.* Sir William Osler, in reply, explained, and not for the first time, what he really said and what he really meant with regard to the use of the lethal chamber after the age of 60. He amused his hearers by saying that he was only referring to persons of professorial rank, maintaining that professors should retain dignity of person, a charm of manner, and an abundance of hair that was not usually associated with advanced middle age. He pleaded guilty to being a bookworm, despite Dr. Trevor's aphorism, and concluded an excellent speech by the daring suggestion that if a medical degree upon fair terms was not soon provided for London students the students should combine and take the matter into their own hands. He suggested that a strike of students would solve the problem in a very short time. Dr. Drury Pennington proposed "The Past and Present Students of the

School," and the toast was replied to by Mr. Ivor Back and Mr. E. F. W. Grellier. The health of the chairman was neatly proposed by Mr. G. R. Turner.

King's College Hospital.—The annual dinner of past and present students of this hospital took place on Oct. 2nd at the Waldorf Hotel, under the presidency of Viscount Hambleden, chairman of the hospital and of the medical school. During the afternoon many past students visited the new King's College Hospital at Denmark Hill, and were conducted over the buildings by the Dean and other members of the staff, being afterwards entertained to tea. Among those present at the dinner were Surgeon-General A. W. May (Director-General of the Medical Department of the Navy), Sir C. Pardey Lukis (Director-General of the Indian Medical Service), Mr. A. Boyce Barrow (consulting surgeon to the hospital), Professor Nestor Tirard (senior physician to the hospital), Professor Sir Watson Cheyne (senior surgeon); Sir Ronald Ross, Sir StClair Thomson, Professor W. R. Smith, Professor Ernest White, and Dr. G. E. Shuttleworth. The health of the chairman was proposed by Sir Watson Cheyne, who spoke in warm terms of the exceedingly satisfactory relations which existed between the committee of management and the staff of the hospital. Not until that night had the chair of that dinner been occupied by a layman, but it was unanimously felt that an exception should be made on this memorable occasion, the eve of the opening of their new hospital at Denmark Hill. He was voicing the feelings of all present in expressing the hope that Lord Hambleden would be the chairman of King's College Hospital for very many years to come. Lord Hambleden in his speech explained the reasons which had caused the delay in completing the new hospital. These were largely due to the unfortunate disputes in the labour world during the last few months. He hoped, however, that in a very few weeks the hospital would begin its work, and he was sure the staff would find the building in every way as perfect [illegible] He desired especially to thank [illegible] the watching committee [illegible] labour which they had given during the work of building. To this was largely due the perfection of arrangements in the new hospital.

Middlesex Hospital.—The annual dinner of past and present students of Middlesex Hospital was held at the Trocadero Restaurant on Oct. 1st. Sir James Kingston Fowler, K.C.V.O., presided, and a large number of those connected with the hospital and their friends attended. Amongst those present were H.S.H. Prince Alexander of Teck, Sir Alfred Pearce Gould, Dr. W. Pasteur, Sir Squire Bancroft, the Mayor of Marylebone (Mr. J. Penton, jun.), Sir James Collie, and Dr. H. Campbell Thomson, Dean of the School. After the Royal toasts had been honoured, Sir James Fowler proposed the toast of "The Middlesex Hospital and Medical School." He referred to certain matters in the history of the school, especially mentioning the union of the hospital and school. Since the school had been managed by a joint committee, consisting of representatives of the managing body of the hospital and of representatives of the honorary staff and teachers at the school, great success had been obtained. Sir James Fowler referred in terms of deep sympathy to the death of Mr. Andrew Clark, who had been greatly attached to the school. He also spoke in high praise of the excellent work accomplished by Dr. Campbell Thomson as dean of the school. Prince Alexander of Teck, in responding to the toast, said that during the past year separate wards had been allocated for the treatment of patients suffering from skin diseases and for diseases of the eye and ear. In the near future it was hoped that the children's ward would be considerably enlarged, and that the sanitary arrangements of the wards in the south-west wing would be improved. Efforts were being made to put into the hands of the medical staff a sufficient quantity of radium in order that they might test its curative properties to the full. Dr. Campbell Thomson, responding for the school, said that a most satisfactory entry of new students had been obtained. Mr. R. Steer Bowker responded for the past students, and the senior Broderip scholar, Mr. A. O. Gray, for the present students. An excellent musical programme added to a most enjoyable evening.

St. Thomas's Hospital.—The annual dinner of the old students of St. Thomas's Hospital was held at the Hotel Cecil on Oct. 1st, the chair being occupied by Dr. H. P. Hawkins. In proposing the toast of the King, the chairman made reference to the close association between the Sovereign and the hospitals, and while proclaiming the late King Edward as pre-eminent in this respect, remarked that King George was a worthy successor. In proposing the toast of "St. Thomas's Hospital and Medical School," the chairman, after referring briefly to the past, turned his attention to the future, and endeavoured to forecast its trend. This, he said, was an era of change. Of course, there had always been change, and the hospital had adapted itself to such changes. But great and revolutionary changes were now taking place, and these would require considerable adaptation. Referring to the three duties of the hospital—to the patients, to teaching, and to research—he spoke of the necessity for the further organisation of research. The growth of specialism—which was inevitable in consequence of the increase of knowledge to such an extent that no man could compass it all—was such that the day of the general physician was rapidly passing, and soon the specialists would invade the wards, as they had already created for themselves special departments. Moreover, the field of work had now shifted from the wards to the clinical laboratories. He expressed the hope that before they met again a scheme for combined work among the various departments would have taken shape. Mr. J. G. Wainwright, the treasurer, in responding, referred to some of the effects of the Insurance Act. It had reduced the number of genuine out-patients, but had increased the number of casualties; the old-time "chronic" had disappeared. Further, a great many cases were being sent in to the special departments by the panel doctors. The advantage to the hospital in having a tuberculosis department in close contact with it was manifest. The massage department was becoming very large and a baby clinic had been lately established. He referred to the report of the Royal Commission on the University of London, and said that if its recommendations were carried out it would materially interfere with all hospitals. He spoke of a legacy left to the hospital by a former almoner who had recently passed away, which would probably be allocated to the reorganised out-patient department. Referring to the expected and deplored cloud hanging over them on this occasion last year, the retirement of Mr. G. H. Makins, he was glad to inform them that the cloud had lifted and that he was yet to remain a while in active service and coöperate in the reorganisation of the out-patient department. He spoke of Dr. Russell's illness and said that he would be back at his work again by the end of November. Finally, he mentioned that during his treasurership 1194 men had passed through the school and gained their diplomas. Dr. E. Stainer, the dean, also responded, and gave some school statistics. An interesting one was that a party of 30 from St. Thomas's Hospital had helped in the Balkan war. Mr. E. F. White proposed the health of the chairman, who responded. The meeting was a record one, nearly 200 being present, among whom were Surgeon-General Sir Launcelot Gubbins (Director-General, Army Medical Service) [illegible] May (Director-General, Medica[illegible] Alderman Sir Thomas Crosby, [illegible] V.O., Dr. F. F. Caiger, Dr. S. M. Copeman, Dr. E. Hopkinson, D.S.O., Dr. S. I. Oddie, coroner for Westminster, and Dr. F. M. Sandwith.

University College Hospital.—The annual dinner for past [illegible] students of University College Hospital Medical [illegible]oyal on Oct. 1st. The chair [illegible] past student of the hospital, Mr. C. J. Bond, of Leicester. The dinner was well attended. The chairman proposed the toast of "The Prosperity of the School" in a felicitous speech full of interesting reminiscences. In his witty reply Dr. G. F. Blacker, the dean, announced the successful state of the school as shown by noteworthy increase in fresh entries and the opening of new departments. Sir Victor Horsley consulting surgeon to the hospital, proposed the health of his friend [illegible]

[illegible] Stewart took the chair [illegible] present students of the [illegible]ool at the Imperial Restaurant, Regent-street, on Oct. 2nd. Proposing the toast of the evening, he referred to the approaching amalgamation of St. George's and Westminster Hospitals.

The principle had been accepted by the governing bodies of both hospitals, whic [illegible] e closely related. The newly amalgam [illegible] d schools would have to build a new [illegible] 500 beds in some part of London. It had been stipulated that every member of the present staff of both hospitals should retain a position equivalent to that which he now held. Dr. T. de Havilland Hall, in reply, said that the question of name had yet to be settled.

The London Hospital.—The annual old students' dinner was held on Tuesday, Oct. 7th, at the Savoy Hotel, Strand, W C., when Dr. Wilfred J. Hadley, physician to the hospital, presided over a good assembly. Dr. Hadley, in his speech proposing "Prosperity to the London Hospital," referred to the effect upon the hospital of the National Insurance Act. The reduction in the number of out-patients would mean, he said, a reduction in teaching material for the student; and so serious was this in the matter of tuberculous patients, who were all seeking sanatorium benefits under the Act, that it might be necessary to institute a tuberculosis department.

MEDICINE AND THE LAW.

Mental Deficiency and Provocation as a Defence to a Charge of Murder.

THE Court of Criminal Appeal had to sit recently during the long vacation in order to hear an appeal from a sentence of death passed upon a man named Thomas Alexander at the Central Criminal Court in September. The prisoner, who had received great provocation from his victim, was found guilty of the murder of a woman, Ellen Clarke, and was recommended to mercy by the jury. On the ground that he was mentally deficient an attempt had been made at the trial to induce the judge to put the case to the jury as one of manslaughter, but this he had declined to do; he explained to the jury the law with regard to sanity and insanity, and the jury did not find that the prisoner was insane when he committed the act, but recommended him to mercy, as mentioned above. It was argued on the prisoner's behalf that a thing might be provocation to a man on the border-line of sanity and insanity which could not be treated as a defence in respect of a man perfectly sane Mr Justice Darling, who delivered the judgment of the Court of Criminal Appeal, said that it was clear that the jury had held upon the evidence that the man was not insane in the legal sense, although they thought him mentally deficient. All sane persons were not of equal mental capacity, and the verdict meant that the prisoner was below the average mentally, but not across the border-line of sanity, and hence there had been a special verdict. The argument with regard to provocation was ingenious, and one which had not been raised before. If such an argument were allowed to carry weight and a man killed another because he had red hair, the act being done by a person mentally deficient, the judge would have to ask the jury whether the murderer, because he was a person mentally deficient, had sufficient provocation in the fact that his victim had red hair to render the verdict one of manslaughter instead of murder. There was no authority to support such a proposition. Only in very exceptional circumstances could mere words constitute such provocation as would reduce murder to manslaughter. The court must hold that the verdict was a proper one and dismiss the appeal, but it expressed no opinion that would limit the Home Secretary's action in the exercise of the prerogative of the Crown.

LONDON SCHOOL OF TROPICAL MEDICINE.—The winter session opened on Oct. 3rd with 60 students on the books. The additional laboratories, rendered possible by the fund raised by Mr. Austen Chamberlain, are being occupied for the first time. The new course in tropical sanitation and hygiene, open to students who have already attended the ordinary course, will be inaugurated this session, the first lectures being held about Oct. 20th. The increased accommodation for resident students has also been made available, and all the rooms have already been let. The annual dinner will be held at Prince's Restaurant, Piccadilly, W., on Friday, Oct. 24th, under the presidency of Dr. F. M. Sandwith.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

City of York.—The report for 1912, signed by Mr. E. M. Smith, school medical officer, and Mr. E. S. Galbraith, assistant school medical officer, is noticeable for the record of work done in the school clinic, which now carries on nearly all the different kinds of work possible to it, and for the presentation of the records of weight and height in conjunction with those of malnutrition. The clinic comprises a "general" department for the supervision of children unfit for school attendance, a treatment department for "minor" ailments, an ophthalmic, and a dental department. There are two whole-time school nurses, five attendance officers, and the whole of the work is well coördinated, the fact that the school medical officer is also medical officer of health materially contributing to this result. The figures for malnutrition show nearly 10 per cent. of children examined to be suffering from this defect; 10 per cent. also "had footgear so defective as to be practically dangerous to the wearer." Also, nearly 10 per cent. are seriously verminous. The "submerged tenth" appears to be a statistical reality. The weights of children are compared with the anthropometric committee's standard, and the total deficiency in weight for the total number of children examined is given as follows:—

—	Children examined.	*Deficiency in total weight as compared with anthropometric standard for various age groups in pounds.*	Number of children who would be represented by this weight deficiency.
1910	2,206	9,450	158 { 82 boys. 76 girls.
1911	4,152	14,645	208 { 106 boys. 102 girls.
1912	3,240	11,450	176 { 88 boys. 88 girls.

The total deficiency in weight represented as above in terms of children (calculated as belonging to different age-groups) thus represents the population of a fair-sized school. In other words, the malnutrition in York causes that city to be 542 children short. The question of the special education of such defective children as the feeble-minded and high myopes is receiving attention, and the whole field of medical inspection is gradually being brought under cultivation.

City of Sheffield.—Dr. R. P. Williams's report maintains the high standard of its predecessors and records the continuous growth of the work and the perfecting of the organisation. A valuable feature is the [illegible] acts Disclosed by Medical Inspection," [illegible] a bird's-eye view of the agencies cooperating in the very complete school antituberculosis scheme. A proposal is made to combat malnutrition by numerous centres for open-air instruction to which debilitated children would be sent. The record of a special investigation is given in Appendix A with regard to boots and clothing "to determine how far the condition of the child was due to the *poverty of the parents* and how far to neglect," but unfortunately this requires considerably more explanation than that given to make it of much value to those ouside the district.

City of Carlisle.—Mr. Joseph Beard's report for 1912 calls attention to sanitary defects in schools; the outside conveniences at one infants' school are described as being "in a disgusting and dangerous condition"; and it is very regrettable that any authority should allow such a state of things to continue. Unfortunately, the school medical officer has little or no direct control over the structure or condition of school buildings. A class for "delicate children" is held at Denton Holme, but it is to be hoped the authority will make up its mind to conserve the health of the children who are not yet delicate by *providing* suitable and sanitary school premises. The cheapness of the open-air school might well be considered if new buildings are required.

C [illegible] —Dr. G. Granville Buckley's report reco [illegible] n inspection clinic, one half-day a week having been set aside for this purpose and 176 cases dealt with. A fair proportion of defective children have been treated, but carious teeth, tuberculous diseases, and various [illegible] as needing further [illegible] nic is held at the town-hall on Monday, Wednesday, and Thursday at 4 P.M., and on Saturday at 10 A.M., and has done useful work. Dr. W. Allen Daley reports that 3966 children were examined in the year, and showed percentages defective: vision, 16 4; four or more unsound teeth, 34 3; and mouth breathers, 14 0 The cost of inspection for the 12 months is given as £489, and the cost per child 9 5*d* It is noted that owing to the migratory habits of parents of children in Standard II. throughout the borough 38 5 per cent. girls and 31 per cent boys had not been educated [illegible]

[illegible] Moore's report [illegible] ners in school, [illegible] dental caries [illegible] ointment of a school dentist, and a whole time officer is to be appointed. The parents attending at the inspections are always handed a note of the height and weight of their offspring, and take the greatest interest in these records. Attention is strongly called to the question of the type used in school books in relation to sight, and the report of the British Association Committee and the comments of the medical officer of the Board of Education are quoted. Children over 9 years should have bold "pica" type and below 9 years "double pica."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose [illegible] lle of this year is estimated [illegible] hs and 4651 deaths were [illegible] d Saturday, Oct 4th. The [illegible] se towns, which had been [illegible] the three preceding weeks, [illegible] the week under notice [illegible] the quarter just ended the mean annual death-rate in these towns averaged 12 7, against a corresponding rate of 11·8 per 1000 in the Metropolis Among the several towns the death-rate last week ranged from 3 6 in Wimbledon, 6 9 in Bournemouth, 7·0 in Swindon, 7·2 in Ilford, and 7·7 in Hornsey, to 20 8 in Aberdare, 21·9 in Sunderland, 23·2 in Tynemouth, 25 2 in Dewsbury, and 26 5 in Great Yarmouth.

The 4651 deaths from all causes were 285 below the number in the previous week, and included 866 which were referred to the principal epidemic diseases, against numbers declining from 1242 to 1081 in the three preceding weeks. Of these 866 deaths, 730 resulted from infantile diarrhœal diseases, 43 from diphtheria, 32 from whooping-cough, 28 from measles, 19 from enteric fever, and 14 from scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 2·5, against 3·3 and 3 2 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 1104, 983, and 927 in the three preceding weeks, further declined to 730 last week; of this number [illegible] Birmingham 38 in I[illegible] Hull, 24 in Sheffield, [illegible] and 19 in West Ham. The deaths referred to diphtheria, which had been 36, 40, and 38 in the three preceding weeks, rose to 43 last week, and included 9 in London, 3 in Portsmouth, 3 in Preston, and 2 each in Cambridge, Great Yarmouth, Bristol, Stoke on-Trent, Birmingham, Salford, and Rhondda. [illegible] had risen from [illegible] to 32 last week; [illegible] 4 in Liverpool, 3 [illegible] Birmingham, Bol[illegible] measles, which h[illegible] ceding weeks, declined to 28 last week, and included 5 in London, 5 in Stoke-on-Trent, 3 in Bradford, and 2 each in Dewsbury, Barnsley, and Sheffield The deaths referred to enteric fever, which had been 10, 13, and 17 in the three preceding weeks, further rose to 19 last week, of which 4 occurred in London and 3 in Stoke-on-Trent. The fatal cases of scarlet fever, which had been 28, 18, and 19 in the three preceding weeks, fell to 14 last week, and included 2 in London and 2 in Birmingham.

The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospitals, which had increased from 2112 to 2570 in the four preceding weeks, had further risen to 2818 on Saturday last; 499 new cases were admitted during the week, against 346, 473, and 508 in the three preceding weeks. These hospitals also contained on Saturday last 977 cases of diphtheria, 194 of whooping-cough, 65 of measles, and 61 of enteric fever, but not one of small-pox. The 1092 deaths from all causes in London were 74 fewer than the number in the previous week, and corresponded to an annual death-rate of 12 6 per 1000 The deaths referred to diseases of the respiratory system, which had been 132, 125, and 134 in the three preceding weeks, declined to 124, and were 67 below the number recorded in the corresponding week of last year.

Of the 4651 deaths from all causes in the 96 towns, 176 resulted from various forms of violence and 346 were the subject of coroners' inquests. The causes of 35, or 0 8 per cent, of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in London and in 13 of its 14 suburban districts; in Manchester, Bristol, Bradford, Hull, Newcastle-on-Tyne, Nottingham, and in 55 other smaller towns Of the 35 uncertified causes of death, 4 were registered in Birmingham, 4 in South Shields, 3 in Liverpool, 3 in Darlington, and 2 each in Stoke on-Trent, West Bromwich, and Southport.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259 600 persons at the middle of this year, 1051 births and 627 deaths were registered during the week ended Saturday, Oct 4th. The annual rate of mortality in these towns, which had been 16 4, 14·4, and 15 1 per 1000 in the three preceding weeks, fell to 14·5 per 1000 in the week under notice. During the thirteen weeks of the quarter just ended the mean annual death-rate in these towns averaged 14·3, against 12·7 per 1000 in the 96 large English towns Among the several towns the death rate last week ranged from 7 5 in *Kilmarnock, 9 5 in Hamilton, and 10 2 in Falkirk, to 17·4* in Greenock, 17 9 in Dundee, and 20 8 in Leith

The 627 deaths from all causes were 26 fewer than the number in the previous week, and included 81 which were *referred to the principal epidemic diseases, against 94 and* 90 in the two preceding weeks. Of these 81 deaths, 43 resulted from infantile diarrhœal diseases, 14 from diphtheria, 8 from measles, 7 from scarlet fever, 5 from whooping-cough, and 4 from enteric fever, but not one from *small-pox* These 81 deaths from the principal epidemic diseases were equal to an annual death-rate of 1 9, against 2 5 per 1000 in the 96 large English towns The deaths of infants (under 2 years of age) *attributed to diarrhœa* and enteritis, which had been 96, 62, and 55 in the three preceding weeks, further declined to 43 last week, and included 18 in Glasgow, 9 in Dundee, 4 in Edinburgh, 4 in Aberdeen, and 3 in Leith *The deaths* referred to diphtheria, which had steadily increased from 5 to 10 in the five preceding weeks, further rose to 14 last week; of this number 5 occurred in Aberdeen, 4 in Glasgow, and 2 in Edinburgh The fatal cases of measles, which had been 12, 9, and 10 in the three preceding weeks, fell to 8 last week, and comprised 7 in Glasgow and 1 in Edinburgh. The deaths attributed to scarlet fever, which had been 4, 4, and 5 *in the three preceding* weeks, rose to 7 last week, of which 2 were registered in Aberdeen. The 5 deaths referred to whooping-[illegible] including 3 in Glasgow, were slightly below the [illegible] in recent weeks Of the 4 fatal cases of *enteric* [illegible] ere recorded in Glasgow, 1 in Dundee, and 1 in [illegible]

[illegible] ths referred to diseases of the respiratory organs, [illegible] been 65, 63, *and 66 in the three preceding weeks*, further rose to 69 last week; 27 deaths were attributed to different forms of violence, against 17 and 26 in the two previous weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 696 births and 415 deaths were registered during the week ended Saturday, Oct. 4th. The annual rate of mortality in these towns, which had been 21·1, 19·8, and 21·0 per 1000 in the three preceding weeks, declined to 18·0 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these Irish towns averaged 18 2 per 1000; in the 96 large English towns the corresponding rate did not exceed 12·7, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 20 1 in Dublin (against 12 6 in London and 14·8 in Glasgow), 13·2 in Belfast, 21·8 in Cork, 21·6 in Londonderry, 23·0 in Limerick, and 38 0 in Waterford, while in the remaining 21 smaller towns the mean death-rate was equal to 17·9 per 1000.

The 415 deaths from all causes were 68 fewer than the number in the previous week, and included 94 which were referred to the principal epidemic diseases, against 120 and 103 in the two preceding weeks. Of these 94 deaths, 78 resulted from infantile diarrhœal diseases, 5 from scarlet fever, 4 from whooping-cough, 3 from enteric fever, and 3 from diphtheria, and 1 from measles, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 4·1 per 1000; in the 96 large English towns the corresponding rate was 2·5, while in the 16 Scotch towns it did not exceed 1·9 per 1000. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 111, 98, and 84 in the three preceding weeks, further declined to 78 last week, and included 26 in Dublin, 15 in Belfast, 8 in Londonderry, 6 in Portadown, 5 in Cork, 5 in Waterford, and 3 in Queenstown. The deaths referred to scarlet fever, which had been 4, 6, and 3 in the three preceding weeks, rose to 5 last week, and comprised 3 in Belfast and 2 in Dublin. Of the 4 fatal cases of whooping-cough, which were slightly below the average in recent weeks, 3 occurred in Galway and 1 in Dublin. The 3 deaths referred to diphtheria and 2 of the 3 deaths to enteric fever were recorded in Dublin. The fatal case of measles was registered in Newry.

The deaths referred to diseases of the respiratory system, which had been 41, 56, and 60 in the three preceding weeks, declined to 34 in the week under notice. Of the 415 deaths from all causes, 121, or 29 per cent., occurred in public institutions, and 7 resulted from various forms of violence. The causes of 16, or 3·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Deputy Surgeon-General Richard Aubrey Fitch has been placed on the Retired List (dated Sept. 27th, 1913).

The following appointments have been notified:—Fleet-Surgeons: J. E. Coad to the *Terrible* and for group of ships of Third Fleet; H. H. Pearse to the *Commonwealth;* F. J. Burns to the *Orion*; E. B. Townsend to the *Vernon;* J. C. Rowan to the *Audacious*, on commissioning, and as acting interpreter in German; and J. E. H. Phillips to the *Leander*, and for duty with torpedo boat destroyers. Staff-Surgeon: F. E Anley to the *Weymouth*, on recommissioning; K. D. Bell to the *Victory*, additional, for disposal, and to the *Audacious*, on commissioning. Acting-Surgeon: P. B. Wallis to the *Victory*, additional, for Haslar Hospital, and for course of instruction at Naval Medical School, Greenwich College, and Royal Naval Hospital, Haslar.

ROYAL ARMY MEDICAL CORPS.

Royal Army Medical Corps Training Establishment: Lieutenant-Colonel Alexander A. Sutton, D.S.O., Royal Army Medical Corps, to be Commandant, vice Colonel George D. Hunter, D.S.O. (dated Sept. 20th, 1913).

Major Gerald S. Mansfield retires on retired pay (dated Oct. 4th, 1913).

Lieutenant-Colonel T. Du B. Whaite has been placed under orders to embark at Southampton for a tour of service with the Northern Army in India, and on arrival will be appointed for duty with the Third (Lahore) Division. Lieutenant-Colonel R. J. Geddes, D.S O., late senior medical officer at Jubbulpore Cantonment, has been appointed an Honorary Associate to the Order of St. John of Jerusalem by His Majesty the King. Lieutenant-Colonel J. Fallon has been appointed to hold charge of the Military Hospital at Lahore on transfer from Dalhousie Cantonment.

Major H. B. G. Walton has been transferred from the Military Hospital at Bareilly Cantonment to Ranikhet. Major W. B. Winkfield has taken up duty at the Military Hospital, Maymyo, Upper Burma, on transfer from Meiktila Cantonment. Major G. Mansfield has been appointed to hold charge of the Military Hospital at St. Peter's Barracks, Jersey, in succession to Lieutenant-Colonel E. Davis, who has retired from the service. Major G. Baillie has been appointed to the Military Hospital at Colchester, on transfer from Yarmouth. Major A. A. Seeds has been transferred from the Military Hospital at Rawal Pindi Cantonment and appointed Senior Medical Officer at Kuldhana, Murree Hills District. Major P. H. Henderson has been appointed to the Military Hospital at Portsmouth, on termination of a tour of duty at the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain. Major S. M. Adye-Curran has arrived home on leave of absence from Sialkot Cantonment. Major S. H. Withers has taken up duty as Senior Medical Officer at Dagshai Cantonment, Simla Hills District. Major A W. N. Bowen has been granted six and a half months' leave of absence home from India. Major J. Dorgan has embarked for a tour of service in South China. An exchange on the roster of service abroad has been approved by the Director-General between Major E. S. Clark, in charge of the Military Hospital at Holywood, and Major A. O. B. Wroughton, in charge of the Military Hospital at Maidstone. Major C. C. Cumming, specialist in bacteriology, has embarked for a tour of service at Malta. Major J. H. R. Winder has taken over medical charge of the Military Families Hospital, Wellington Lines, Aldershot. Major J. W. West has been appointed Specialist in Operative Surgery to the Second (Rawal Pindi) Division of the Northern Army in India. Major H. E. M Douglas, V.C., D S.O, has been placed under orders to proceed to Egypt for a tour of service. Major G. St. C. Thom has taken up duty as Deputy Assistant Director of Medical Services (Mobilisation) to the Second (Rawal Pindi) Division of the Northern Army in India. Major T. J. Potter has been appointed Clinical Pathologist to the Military Hospital at Cairo. Major C. T. Samman has been appointed Specialist in Mental Science to the Fifth (Mhow) Division.

Captain J. E. Powell has been appointed to the Military Hospital at Hilsea. Captain G. H. Rees has been transferred from medical charge at Mosney Camp to the Military Hospital at Belfast. Captain M. Keane has been placed under orders to embark for a tour of service with the Ninth (Secunderabad) Division. Captain O. Ievers has been appointed to the Military Hospital at Chatham. Captain T. T. H. Robinson has been transferred from the Military Hospital at Lichfield to Strensall for a tour of duty. Captain G. A. Kempthorne has been transferred from the Royal Army Medical Corps Camp of Instruction at Tidworth Park, Salisbury Plain, to Tregantle Fort. Captain R W. D. Leslie has been transferred from the Military Hospital at Gosport to Romsey. Captain M. C. Wetherell has been appointed to Kildare for duty at manœuvres. Captain L. Cotterill, instructor in musketry at the Royal Army Medical Corps Depôt, has been appointed to the First (Peshawar) Division of the Northern Army in India. Captain A. A. Meaden has been appointed to the Eastern Command for duty at the Military Hospital, Colchester. Captain W. H. Forsyth has been transferred from Tidworth Park, Salisbury Plain, to Netheravon for duty at the Cavalry School. Captain J. H. Campbell has been appointed to the Scottish Command for duty at the Military Hospital, Edinburgh. Captain H. C. Sidgwick has been appointed to the Royal Herbert Hospital at Woolwich. Captain J. McKenzie has been placed under orders for duty with the Eighth (Lucknow) Division of the Southern Army in India. Captain N. Low has been appointed to the Military Hospital at Cosham. Captain G. G. Tabuteau has qualified at the Royal Army Medical College for appointment as Specialist in Operative Surgery. Captain R. H. L. Cordner has been appointed to the Aldershot Command. Captain H. J. Crossley has been placed under orders to embark at Southampton on Oct. 22nd for a tour of service in India and has been placed under orders for duty with the Seventh (Meerut) Division of the Northern Army in India. Captain R. G. Meredith has taken up duty in the London District. Captain F. E. Roberts has been appointed to the Military Hospital at Shorncliffe and has been selected for appointment as Specialist in State Medicine. Captain T. H. Gibbon has taken up duty at King George V. Military Hospital, Dublin. Captain F. C. Lambert has been placed under orders for duty with the Sixth (Poona) Division of the Southern Army in India. Captain J. E. Hoar has been appointed to the Military Hospital at Chatham. Captain A. H. Jacob has been transferred from the Military Hospital at Dublin to Wicklow and appointed to hold medical charge at the Murrough Camp. Captain C. W. O'Brien has taken up duty in the London District. Captain R. E. Humfrey has joined the Military Hospital at Cork for a tour of duty. Captain A. D. Fraser has been selected for appointment as Specialist in Bacteriology. Captain R H. MacNichol has been placed under orders to embark for a tour of duty in Malta.

Lieutenant B. H. H. Spence has been appointed to the Second (Rawal Pindi) Division. Lieutenant W. F. Christie has taken up duty in the Straits Settlements. Lieutenant S. F. Sykes has been placed under orders for a tour of service in India, and on arrival will be appointed to the Third (Lahore) Division of the Northern Army. Lieutenant C. C. Jones has taken up duty in the London District. Lieutenant C. J. H. Little has joined the Northern Command. Lieutenant W. Stewart has relinquished duty at the Military Hospital, Colchester, and embarked for service with the Seventh (Meerut) Division of the Northern Army in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel V. Drake-Brockman, Agency Surgeon at Meywar, has been placed under orders for transfer to Bhagelkhand.. Lieutenant-Colonel W. Ronaldson Clark has been appointed to hold civil medical charge at Jullundur. The services of Lieutenant-Colonel W. E. Jennings have been placed at the disposal of H.E. the Commander-in-Chief in India.

Major A. Murphy has arrived home on leave of absence from India. Major J. Watson has been selected for appointment as Agency Surgeon to the Eastern States of Rajputana by the Foreign Department of the Government of India. Major H. A. F. Knapton has been appointed to officiate as Sanitary Commissioner to the Government of Bombay Presidency. Major C. G. Webster, of the Madras Medical College, has been granted two years' combined leave of absence home from India. Major W. M. Anderson, second-class agency surgeon, has been appointed Residency Surgeon to the Gwalior State. Major A. G. Sargent has been appointed Superintendent of the Lunatic Asylum at Rangoon, in succession to Major W. H. Cox, D.S O, granted leave of absence home from India. Major E E. Waters has been appointed to officiate as Professor of Materia Medica at the Government Medical College, Calcutta, during the absence on sick leave of Major D. McCay.

Captain H. P. Cook has been appointed to the United Provinces of Agra and Oudh for employment in plague prevention duty. Captain J V. Macdonald has been transferred from duty under the Home Department of the Government of India and reverted to military employment. Captain R. G. Croly has embarked at Bombay in medical charge of troops on board the s s. *Barjora* for service at Muscat. Captain H. N. H. Melhuish, plague medical officer at Rohtak, has been granted combined leave of absence home from India for six months. Captain N. S. Sodhi, plague medical officer at Gurgaon, has been transferred to the Ludhiana District. Captain H. C. Keates has been appointed to hold civil medical charge at Campbellpore on return to duty from leave of absence. Captain S. H. Lee-Abbott has been appointed Civil Surgeon at Ferozepore on termination of leave of absence. Captain E. T. Harris, civil surgeon at Toungoo, has been transferred to Bassein and appointed to hold civil medical charge in succession to Captain E. A. Walker. The services of Captain T. G. F. Patterson have been placed temporarily at the disposal of the Government of Bombay Presidency for civil medical employment. Captain J. M. A. Macmillan, civil surgeon at Hoshangabad, has been granted privilege leave of absence. Captain J. Cunningham has been placed on special duty under the Director-General I.M.S., at Barisal Jail, in connexion with the prevalence of dysentery in Eastern Bengal jails.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants to be Captains:—Charles M. Page (dated Sept. 14th, 1913). Edward T. Holland (dated Sept. 28th, 1913). William M. Biden (dated Sept. 30th, 1913).

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd Lowland Field Ambulance, Royal Army Medical Corps: Lieutenant James Young to be Captain (dated August 8th, 1913).

North Midland Mounted Brigade Field Ambulance, Royal Army Medical Corps: Lieutenant William M. Hewetson resigns his commission (dated Oct. 8th, 1913).

Welsh Border Mounted Brigade Field Ambulance, Royal Army Medical Corps: Major Alexander G. Hamilton to be [illegible] 18th, 1913).

[illegible] Royal Army Medical Corps: [illegible] ller, from the 6th London [illegible] my Medical Corps, to be Captain in the permanent *personnel* (dated Sept. 10th, 1913).

ROYAL NAVAL MEDICAL SERVICE: EXAMINATION FOR APPOINTMENTS AS ACTING SURGEONS.

At the examination for the Naval Medical Service held on Sept. 29th and Oct. 1st and 2nd, 13 candidates were successful and obtained the following marks:—

	Marks.
[illegible]	1703
[illegible]	1686
[illegible]	1643
[illegible] School, Dublin	1578
[illegible]	1515
[illegible]	1483
[illegible]	1470
[illegible]	1455
[illegible]	1455
[illegible]	1435
[illegible]	1418
[illegible] Ireland	1380
H. J. Hopps, M.B., Edinburgh University	1338

The maximum number of marks obtainable is 2400.

DEATHS IN THE SERVICES.

Deputy Surgeon-General Nathaniel Norris (late A.M S), at his residence, Chester, in his eighty-third year. He entered the service in 1855, and served with the Jowaki expedition in 1877 (medal and clasp). He was in the Afghan war of 1878-80, and was medical inspector on the lines of communication in the Soudanese Nile expedition of 1884-85 (medal with clasp and bronze star).

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Medical Session.

Professor A. E. Boycott gave an address on Oct. 1st in the Medical School to inaugurate the session. He chose for his subject "The Aim of Pathology." Professor W. Stirling, in opening the course of lectures on physiology, gave an address under the title "Can you Believe Your Eyes?" The address was illustrated by many lantern slides of geometrical and other optical illusions, as well as by optical illusions of varying characters projected on the screen. He said that the wise saying of Solomon, "Hardly do we discern the things that are on earth, and the things that are close at hand we find with labour," still holds true. Illusions make up a large part of our daily life, while the fusion and continuity of impressions which give rise to many optical illusions are represented by the action of the thaumotrope and its latest offspring, the cinematograph. The light of the body is the eye, yet the great majority of mankind either do not see the fraction of w[illegible] their organs of vision or they fail to [illegible] hat is presented before them. Rusk[illegible] of vision that dwells in a man is the [illegible] man, and "to see clearly is poetry, pr[illegible] all in one." The [illegible] of sight is the one in which we believe most impli[illegible] and the one which gives us the largest store of information regarding the world in which we live. So confident are we that what we see must be true, that the expression "Seeing is believing" has passed into a proverb. The possible field of error is larger in the case of vision than in any other sense-organ. Many illusions have their roots in normal mental life. If on seeing an object we believe, and the belief is demonstrably wrong, there is an illusion. Pictorial art is largely based on illusions. In architecture the ancient Greeks corrected the unpleasant optical illusion which columns with perfectly straight edges suggest—namely, the appearance presented by the shaft of being narrower at the middle of the column. They therefore gave to the middle of the shaft an increased diameter—a process known by the name of entasis. The Greeks also applied the same correction to the apparently vertical sides of a tower. In the course of his address Professor Stirling showed experiments to illustrate the after-effects of scene movements, such as the effects produced by gazing for a short time at a waterfall and then turning our eyes to the contiguous rocks, when the rocks appear to move upwards with a velocity equal to that of the falling water. The production of coloured fringes from non-coloured objects was illustrated by Benham's spectrum-top. The subjects of irradiation, contrast, direction of lines, and objects seen under familiar conditions were presented and explained.

Professor Stirling in addition on Oct. 3rd gave a demonstration of new cinematograph films to students and medical men on "Some Applications of Cinematography in Physiology, and more especially in the Teaching of Physiology." Professing himself to be a convinced believer in the value of cinematography in the teaching of physiology, the lecturer presented first a series of films to illustrate the movements of microscopic animals by the method known as "dark-ground illumination"; then he showed the protoplasmic movements of amœba and of some animalcules which are propelled by means of ciliary motion. The same method was adopted to show the movements of the white cells of the blood of the carp, which have their nucleus at the hind end of the cell. The circulating movements of the protoplasmic granules and chlorophyll granules within certain water plants were projected on the screen. The actual growth of the protoplasm of slime-fungi at the circumference of the organism, as well as the remarkable reversible movements in the protoplasm itself, could be seen by the whole audience. The astonishing corkscrew-like movements of the organisms known as spirochætæ were next shown. The circulation of the blood in a small crustacean—an Isopod—was demonstrated. The latest advance in cinematography which is known as "ultra-cinematography" was also illustrated. In this method the successive phases of movement are "slowed down." Impressions of a movement, such as walking, running, or the flight of a bird, are taken at the rate of 180 images per second. These images were projected in the ordinary manner—i.e., 16 per second, so that the audience could analyse with perfect ease the successive movements of the human limbs in locomotion, as well as the graceful movements of a pigeon flying freely in the open air under perfectly normal conditions. The beating of the heart in the open chest, when normal and during asphyxia, was projected, the movements being slowed from 10 to 20 times their normal speed, so that the successive stages of these movements could be analysed by the unaided eye. It is now well known that living embryonic tissues can be cut from the living body and can be cultivated in appropriate aseptic media for many days after removal from the body. The study of surviving excised tissues *in vitro* has been specially prosecuted in America by Harrison, Burrows, Carrel, Lambert, and others, and in France more especially by Levaditi and Comandon. Professor Stirling showed a small fragment of a spleen removed from a developing chick, which was placed in a sterilised culture medium and kept at 37° C. The tissue lives for many days, and the audience could see the growth of the tissue itself, as well as the leucocytes emigrating from the piece of spleen and moving freely in the surrounding medium. A fragment of the embryonic heart of a chick showed the actual outgrowth in a radiate manner of [illegible] cells into the surrounding medium. [illegible] of the cells ceased to [illegible] and before the eyes of [illegible] to two new independent cells. The [illegible] ich a minute fragment of the heart fills the field of the microscope with fusiform cells in about eight hours.

Recommendations for Ambulance Provision.

In order to extend the ambulance service amongst the poorer classes the chief constable recommends that on the production of a medical certificate the free use of an ambulance be allowed to all householders who have, from all sources, an income of less than 35*s.* a week coming into the house. To secure the coöperation of medical men, and to prevent abuse as far as possible, practitioners should be supplied with a book of printed certificates, so that when called to a case requiring an ambulance they could fill in the certificate, giving the patient's full name and address, nature of disease, hospital to be conveyed to, and stating that in his opinion it was a case for free removal, and was non-infectious.

Mr. J. Carter Bell's Bequests.

Mr. Joseph Carter Bell, of Higher Broughton, public analyst for the county of Chester and for the county borough of Salford, after certain preliminary bequests, has divided the residue of his estate, approximately £30,000, into sixtieths, leaving three-sixtieths each to the Manchester Royal Infirmary, the Salford Royal Hospital, and the London Orphan Asylum at Watford. The remainder he bequeathed to relatives.

Oct. 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Treatment of Tuberculosis in Edinburgh.

To meet the increased demand for accommodation for phthisis patients at the city hospital for infectious disease the public health committee recently decided to erect two large open-air shelters there, each to accommodate 60 patients. Each is in the form of an elongated shed with an entirely open front, which can be easily partially enclosed by means of screens. The administration accommodation is very complete, comprehending excellent kitchen and bathrooms, and there is a large dining hall and also recreation room attached to each shelter. There is now accommodation at the city hospital for 180 cases, and with these new quarters it will be possible to have the early cases—for whom treatment must now be provided under the National Insurance Act—living under a different roof from the more advanced cases, for whom alone up to the present provision has been made at the hospital. There are at present, therefore, 92 vacant beds.

The Declining Birth-rate in Edinburgh.

An interesting return in this connexion is that made by the Edinburgh school board regarding enrolments in the day schools, which show a decrease of 748 as compared with September of last year. This fall off in numbers has taken place in the elementary schools alone, the returns for the higher grade showing a slight increase. One notes that out of 57,170 houses in [illegible]) or under, no less than 32,377 [illegible], which is an increase of 1798 houses in this category as compared to this state of affairs last year. The special schools showed an increase in enrolments of 12, the total being 496.

Sanatorium Benefits in Midlothian.

A statement issued by the Insurance Committee for the county remarks upon the small demand for treatment in the sanatorium. During the year there were only 32 applications, and as five were refused as being unsuitable for domiciliary or sanatorium treatment, but 27 patients were taken charge of. As the committee is allowed 9*d.* per head over the number of insured persons, which was taken as 35,000, a considerable surplus is carried over, the expenses to the committee for cases treated being only £469 as regards sanatorium benefit.

Royal (Dick) Veterinary College, Edinburgh.

At the opening of the new session of the Royal (Dick)

Veterinary College, it was announced that operations for the erection of the new college buildings were progressing rapidly, and would be pushed on with all speed in order that the classes might be transferred from the old buildings at an early date. The cost of the new buildings is estimated at £65,000.

Memorial to a Tiree Medical Man.

An interesting ceremony took place at Baugh, Island of Tiree, on Sept. 29th, the occasion being the formal inauguration of the memorial recently erected to the late Dr. Alexander Buchanan, of Tiree. The monument is composed of a shaft of Aberdeen red granite, 10 feet high, resting on a solid granite pediment, encircled in a rough cairn of sea-worn boulders, the whole erection rising to a height of 17 feet from the ground. The eastern face of the pediment bears the following inscription:—"In loving memory of Dr. Alexander Buchanan, born at Callander 4th October, 1835, died at Tiree 29th April, 1911, for 51 years the medical officer and loved and valued friend of the islanders." At the unveiling ceremony reference was made by various speakers to the love and respect in which Dr. Buchanan had been held throughout the island.

The Tuberculosis Order in Glasgow.

The executive committee formed by the corporation of Glasgow under the Diseases of Animals Acts have brought forward a proposition that certain work should be transferred from the health department to their department with a view to assisting the veterinary inspector in carrying out the Tuberculosis Order, 1913. The Order from the Board of Agriculture and Fisheries aims at the destruction of bovine animals suffering from tuberculosis. If it is to be effectively carried out there should be a regular inspection of the dairies and byres within the city. The work of inspection, it is suggested, will be similar to what is being done at present, but in addition to that work arrangements will have to be mad[illegible] post mortem examination, and [illegible] bovine animals (not cows alon[illegible]rcasses. The veterinary inspector is to be authorised to deal with these matters, but where the owner does not consent to the slaughter of a tuberculous animal or its value exceeds £30 the inspector is to advise the town clerk, who shall communicate with the Board of Agriculture and Fisheries.

Special Reservists and Measles; the Outbreak in the Outer Islands.

At a meeting of the public health committee of Inverness-shire held on Sept. 30th, a letter was read from the headquarters, Scottish Command, in reference to the introduction of measles to the outer islands by special reservists. A resolution anent the matter passed at the last meeting of the county council had been forwarded to the chief medical officer of health, headquarters, Scottish Command. The following points were noted in the communication: 1. As the maintenance of the health of the troops is of very great importance, these soldiers are under constant and close medical supervision while in camp. The outbreak of infectious disease is thus discovered as soon as possible after the appearance of initial symptoms, and contacts are speedily isolated. 2. Every endeavour is made to ensure that [illegible] to mix with [illegible]y taken for [illegible]ial Reserve [illegible] complaints of the spread of [illegible] been received from other [illegible] men actually sick can be detained, it is not in the power of the military authorities to detain healthy men or contacts beyond their training period. To do so would require a special Act of Parliament. I may mention also that the financial aspect of this part of the question presents insuperable difficulty. The letter goes on to regret the occurrence of the epidemic referred to by Dr. Murdo T. Mackenzie, and to give assurance that every effort will be made in the future by the military medical authorities, as far as lies in their power, to prevent the repetition of such an unfortunate incident.

Diphtheria Epidemic in Aberdeen.

A severe epidemic of diphtheria is at present raging in Aberdeen. Fortunately the majority of the cases have not been of a severe type. On the advice of the medical officer of health the water-supply at the various schools in the city was turned off on the 26th of last month. At a meeting of the Aberdeen school board held on Sept. 26th the chairman, in answer to a question, said that he thought it was rather the use of the drinking mugs at the schools that was objected to than to the use of the water itself.

The late Dr. Gavin Tennent.

Dr. Gavin Paterson Tennent, whose death was recorded in these columns on Sept. 27th, bequeathed £25,000 to the University of Glasgow. A point in his life also, I think, deserves further mention. In his younger days he had a large experience of relapsing fever, a disease known only by name to the majority of the profession at the present day. In 1867, the year in which he graduated, there were many Glasgow practitioners who remembered the epidemic of relapsing fever in t[illegible] in eight months. [illegible] the city, Dr. Tenn[illegible] hospital then in Kennedy-street. At the end of October of that year the routine work of the wards became so heavy that elaborate clinical records could no longer be compiled, but Dr. Tennent had already collected copious data relative to 352 successive cases, and published an analysis of them in the *Glasgow Medical Journal* for May, 1871.

Oct. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Medical Committee.

THE new Irish Medical Committee has issued a circular, copies of which are to be sent to the members of the profession by the secretaries of the various Local Medical Committees. An account of the formation of the Irish Medical Committee is given, and attention is drawn to the critical position in which Irish doctors have been placed by the statement made by Mr. Lloyd George in the House of Commons on August 14th, to the effect that, if a scheme could be devised for certification which was satisfactory to the medical profession and the Approved Societies, he would be prepared to ask Parliament to increase the grant by such amount as may be necessary, subject to the limit of 2*s.* 6*d.* per insured person which has been imposed. Further, it is pointed out that in the struggle which is likely to take place in Ireland over the extension of medical benefits—based on the recommendations of the Majority Report of the Treasury Interdepartmental Committee—the medical profession will have no security, except in its own united action, against the gravest injury to its status, its interests, and the efficiency of its work. An appeal is therefore made for financial support for the expenses of this struggle, and it is expected that members of the medical profession will forward not less than £1 as their present subscription. The difficulty is that the expenses of the Local Medical Committees—which are not small—must be met in the first instance.

Infantile Mortality in Dublin.

The high rate of infantile mortality in Dublin during the past few weeks gives cause for anxiety. In particular, the prevalence of diarrhœa and enteritis is alarming. To some extent the unusually dry season is responsible, but it cannot be doubted that the distress consequent on the industrial dispute has made matters much worse. In the four weeks ending Sept. 27th there were 107 deaths of children under 2 years of age from diarrhœal diseases. It is noticed by residents in Dublin that the number of flies has been abnormally great this autumn, and [illegible] a factor in the spread o[illegible] the propagation of flies [illegible] the cleansing of lane[illegible] corporation. The streets and lanes in charge of the corporation are, however, far from clean, and no attempt is made to enforce the law against private owners. An instructive correspondence has passed between the public health committee and another committee of the corporation, the cleansing committee. The former requested the latter to water the streets before sweeping, in order to keep down the dust. The cleansing committee replied that the water in the city reservoir was low, and economy was required. In response the public health committee pointed out that water could readily be obtained from the canals for watering the streets. Of this suggestion no notice was taken, and on the rare occasions when the streets are swept the dust is raised in clouds to the tops of the houses.

Treatment of Tuberculosis in Belfast.

The scheme for the treatment of tuberculosis devised by the corporation of the county borough of Belfast having now been approved of by the Local Government Board for Ireland, and the Treasury having now written to guarantee the share to be borne by them, which will amount to £16,745 13*s.* 4*d.*, according to the estimate, the arrangement will shortly come into being. The White Abbey Sanatorium, built and at present run by the Belfast board of guardians, is to be taken over by the city corporation. In the meantime, a very keen canvass is going on for the post of chief tuberculosis officer, who is to have a salary of £600 a year.

Oct. 7th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Académie de Médecine.

THE permanent secretary of the Académie de Médecine has been authorised to accept in its name the legacy of M. Pannetier, made in his will dated Dec. 10th, 1908. This legacy consists of 100,000 francs, the proceeds to be devoted to the establishment of an annual prize for the author of some discovery in medicine or surgery, or to any person who shall be distinguished for the application of recent discoveries. If during one or more years the prize cannot be awarded, the interest is to be added to the capital, to augment the proceeds in the ensuing years. The sum bequeathed is to be invested in French three-per-cents. in the name of the Académie de Médecine, the destination of the proceeds being duly recorded.

The Sale of Poisonous Substances.

Oct. 7th has been set aside for discussion at the Académie de Médecine of a proposition advanced by many of the members for a Bill to modify the ordinance governing the sale of poisonous substances. At present no one who does not hold a pharmacist's diploma or is not authorised by the laws in force to dispense medicines under exceptional conditions to his patients may supply for use in human or veterinary medicine the poisonous substances contained in Table A, which may be dispensed only on the prescription of a medical man, of a veterinary, or of persons authorised especially to prescribe them. The author of the prescription must sign and date the prescription and give his name and address and the doses of the said poisons, and must indicate their mode of administration. Ergot and corrosive sublimate may be supplied on the prescription of a midwife. In default of any contrary indication by the author, every prescription containing poisonous substances in Table A may be repeated by pharmacists, but prescriptions containing aconitine or its salts, hydrocyanic acid, potassium cyanide, digitaline, hashish and its preparations, strophanthine, veratrine or its salts, may not be repeated either by the pharmacist who first dispensed the prescription or by any other. The same prohibition extends to prescriptions ordering the alkaloids of opium or cocaine, as well as their salts or derivatives, but only when these products are prescribed by themselves or in the form of solutions for injection. It applies also to powders with a cocaine base or one of salts containing these substances in a proportion of or above 1 per cent. Pharmacists must enter their prescriptions on a register and enter also renewals thereof. When they retain the prescription they must return to the patient a signed and dated copy. These articles of the law leave many loopholes. It appears insufficient to authenticate prescriptions by signing and dating them and legibly appending the name and address. It would be a good plan to enjoin the use of a stamp or an adhesive wafer bearing the name and address of the medical man, together with his number on the official register. It is also very dangerous for the medical man as well as for the pharmacist, and opposed to the interests of the public health, to permit the repetition of any prescription containing poisonous subjects without renewal by its author; first, because the prescription was written to apply only to a determined condition, and the medical man alone can determine other cases in which the prescribed medicaments are suitable; next, because, since it is forbidden to supply the drugs without a prescription from a medical man, it may be equally or even more dangerous to repeat them without the advice of him who is the sole judge of the fitness of repeating them. Dr. Desesquelles therefore proposes to replace this entire article of the law by the following: In the absence of any contrary indication by the author of the prescription, no prescription containing any of the poisonous ingredients in Table A may be repeated by pharmacists. The supplying of aconitine or its salts, of hydrocyanic acid, of potassium cyanide, digitaline, hashish or its preparations, must not be repeated without a fresh prescription from a medical man, the prescription being dated and legibly signed and bearing the medical man's name and address.

The Collège de France.

The Minister of Public Instruction has signed the decrees whereby the number of chairs in the Collège de France is reduced from 43 to 40, the suppression to take place as the chairs fall vacant. The annual salaries of the 40 professors of the college are fixed at 12,000 francs.

Conferences on Electricity, X Ray, and Radium.

The Société des Médecins Chefs des Laboratoires de Radiologie et d'Electro-radiothérapie des Hôpitaux de Paris organises twice yearly, in November and May, a series of theoretical and practical conferences on electricity, X ray, and radium, lasting for one month. The first series will take place from Nov. 3rd to Dec. 2nd of this year in the amphitheatre of the Hôpital de la Pitié, 83, Boulevard de l'Hôpital, for the theoretical part. The practical part—that is to say, practical demonstrations in electrology, X ray work, and radium work—will be held in the mornings in the laboratories of radiology and of electro-radiotherapy of the Paris hospitals. Those attending will be divided among the various hospitals in parties of ten at most. The parties will be formed at the close of the conference on Monday, Nov. 3rd. There is no subscription. Intending entrants must register with Dr. Delherm, Hôpital de la Pitié, or with Dr. Aubourg, Hôpital Boucicaut.

Attempted Murder of a Medical Man by a Madman.

Dr. Philippe, who is at present doing duty for a *confrère* at Saint Mandé, was called to see a man aged 25 Shortly before midday the medical man, on presenting himself at the address given, was received by the patient, who took him into the dining-room and offered him a paper to read. The paper contained an inconsequent jumble of words. Unsuspectingly the doctor examined the patient, auscultated him, and put a few questions. Suddenly the patient seized a couple of knives and threw himself on the doctor. The latter seized his aggressor by the wrists and with a violent effort forced him into a corner, then hurriedly escaped, not, however, before he had been wounded, though only slightly, on the hand, the left eyebrow, and the upper lip.

Burglars at the Hôpital de la Charité.

An attempt has been made to rob the strong room of the Charité, but the thieves succeeded only in carrying off some 20 francs that they found in an office drawer. An unsuccessful attempt was made to open the strong room with a false key. It has been clearly shown that the thieves could not have broken in at night, but must have been in the building, and are probably there now. Both honest men and rogues are taken care of at the hospital. Pay-day for the *personnel* is on the 29th of each month. On the 28th the cash—some 50,000 francs—is brought from the bank and placed for the night in the safe. The thieves were certainly acquainted with this detail, since they attempted their *coup* on that day. But the 28th being a Sunday the money had not been brought, and the strong room contained only the remainder from the last pay-day.

Oct. 6th.

GUILD OF ST. LUKE.—At the annual service of the guild, which will be held in St. Paul's Cathedral on Tuesday, Oct. 21st, at 7.30 P.M., the sermon will be preached by the Rev. Canon Arnott, F.R.C.S., rector of Beckenham. Admission will be by ticket, to be obtained from the Provost, Mr. George Cowell, F.R.C.S., 24, Harrington-gardens, London, S.W. A stamped addressed envelope should be enclosed with the application.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Statistics of Cancer.

ACCORDING to Professor Behla, one of the medical members of the Prussian Statistical Office, the number of deaths from cancer has again increased in 1912 as compared with the preceding year, 30,045 deaths from cancer having been reported in 1912 against 29,473 in 1911. The increase in cancer mortality has been continuous during recent years, whilst the death-rate from tuberculosis is constantly decreasing. New methods of treatment have thus failed to produce a decrease in the mortality, and it will be of interest to see from future statistics whether this will continue to be the case after the introduction of modern radiotherapy. Professor Behla draws attention to the remarkable fact that the cancer mortality of the year is always greatest in the autumn.

A Municipal Subvention to the Berlin Medical Society.

The Berlin Medical Society has hitherto not been in possession of premises of its own, the Langenbeck House, where the meetings take place and where also the offices and library are accommodated, being the property of the German Surgical Association, and only rented from them. The Langenbeck House has long since proved much too small for the increasing number of members of the Medical Society, and the society has therefore decided to build a new house of its own, to be called the "Virchow House." The purchase of a site in the medical quarter of Berlin, however, has exhausted the funds at the disposition of the society, so that but little money is left for the cost of building. The committee of the society some time ago petitioned the municipal authorities of Berlin to grant to the society a subvention on account of the valuable work done by the society for public health. The town council has, indeed, after a thorough discussion, decided to grant the request and to give to the society an annual sum of £500 for five years, beginning with Oct. 1st, 1914, and further, to lend the sum of £50,000 on mortgage on the premises. In this way the Medical Society is at once relieved from its financial difficulties and will be able to begin building the new premises. This generous decision of the Berlin municipal authorities is highly appreciated in medical quarters. The plan of co-operating with the German Surgical Association in constructing a large house to be used in common has been abandoned, the negotiations for that purpose not having led to any practical result, although the Langenbeck House also is much too small for the Surgical Association, so that their last two meetings had to be held outside the Langenbeck House in a large concert hall.

The Noise in Modern Hotels.

Professor Oppenheim, the well-known specialist for nervous diseases, has been drawing public attention to certain drawbacks connected with [illegible] great progress made in [illegible] He refers to the noise [illegible] water arrangements for a great number of bathrooms and lavatories. Matters are made worse by the thinness of the partitions between the hotel rooms, which allow every noise in the neighbouring rooms to be heard, notwithstanding double-doors and double-windows. The situation of the leading hotels in busy thoroughfares does not favour quietness, and in the back rooms the noise is sometimes as annoying as it is in front. But the greatest nuisance of all is the excessive supply of music. Formerly musical performances took place only in the evening and in certain hotels; nowadays every hotel, from the fashionable ones in the great cities to the more unpretending inns in remote mountain places, has its house band, which performs at least twice a day. Music, as Professor Oppenheim says, is truly a great delight, but only under certain conditions, and the individual hotel resident should have the choice whether he wishes to hear music or not, whilst under present conditions he has no means of escaping it, even should he prefer to seek quietude in a retired corner. The hotel [illegible] ggests, should discuss the [illegible] gress; he is certain that [illegible] of the guests, especially [illegible] if they would alter the [illegible]

Oct. 6th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

An International Congress against Alcohol at Milan.

THIS is a season of congresses, of which perhaps the most important has been the International Congress against Alcohol, inaugurated at Milan on the 22nd of last month. The Onorevole Falcioni, Under Secretary of State, represented the Government and welcomed the delegates, who included representatives of 28 different countries. The committee had kept in view the most important point of the alcohol question as it affects this country, and instead of inviting the Congress to philosophise over the vice of inebriety and enthuse over the virtues of abstinence they had placed before it the economic problem, vital to Italy, of the utilisation of the fruit of the vine apart from the production of alcohol. It appears that the work of Italians has gone far towards the solution of this problem in the preparation of a grape juice concentrated by a cold process. This gives an economical, pleasant, and nutritious drink containing phosphorus in combination as lecithin and nuclein in proportions much higher than in wine. Experiments have shown the ease with which it is assimilated and proved its nutritive value for children and delicate subjects.

The Congress of Sciences at Siena

Another interesting congress has been that of the sciences held at Siena last week. Medical sciences were well represented. Professor Sclavo's address on the Rights of Hygiene was an outspoken criticism on the state of affairs obtaining here. He told an amusing story of a doctor who, having obtained funds for the acquisition of a site for a home for children with a tendency to tuberculosis in a fine position overlooking the sea, received a summons to the prefect, who advised him to drop the project as he would never allow him to open an establishment of such a kind, *so full of danger to the fish in the sea below!* Professor Sclavo found both medical men and engineers deficient in education in matters of public health, and deplored the great waste of public money which this ignorance has caused. Professor Centanni reported some original observations on the behaviour and development of tissues in artificial conditions. Making use of a modification of Carrel's technique, he had studied the means to stimulate the growth of tissues and to produce pathological formations. He expressed the conviction that this line of research promised important practical results. For the entertainment of the congress the municipal authorities arranged a third performance of the "Palio," the mediæval horse races, of which the usual two performances take place in July and August in the Piazza del Campo.

Oct. 4th

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Canadian Public Health Association.

AT the third annual congress of the Canadian Public Health Association, held in Regina, Saskatchewan, on Sept. 18th, 19th, and 20th, under the presidency of Dr. John W. S. McCullough, chief health officer of Ontario, a resolution was adopted affirming that advanced cases of tuberculosis could be treated in general hospitals without the danger of infection to other patients, providing proper arrangements were made, and copies were ordered to be sent to the Provincial Governments, asking that provision be made in all hospitals receiving Government aid. A resolution was adopted also asking the Dominion Government to take into consideration the danger to the public health through the yearly increasing number of immigrants from European countries into Canada. The following officers were elected for 1914: President, Dr. M. M. Seymour, Regina. Vice-presidents, Dr. J. D. Page, Quebec; Dr. T. Aird Murray, Toronto; and Dr. Duncan Anderson, Toronto. General secretary, Dr. Lorne Drum, Ottawa. Treasurer, Dr. G. D. Porter, Toronto. Fort William and Port Arthur will be the place of meeting in 1914

Sanitary Services Convention, Quebec.

The fifth annual conference of the Sanitary Services of the Province of Quebec was held in Montreal during the week ending Sept. 20th, and presided over in the absence of the chairman of the Quebec Board of Health, Dr. E. P. Lachapelle, by its secretary, Dr. E. Pelletier. Dr. J. E. Laberge, of Montreal, insisted that instruction in hygiene should be made compulsory in all the schools of the province. He outlined 12 lessons, which could be subdivided into four parts, so that ample time could be devoted to all phases of the subject. At an evening session, Dr. T. A. Starkey, Professor of Hygiene in McGill University, gave a public lecture on the Responsibility of Municipalities in carrying out Sanitary Measures, which was followed by another lecture by Dr. C. N. Valin, Professor of Hygiene in Laval University, on the Advantages of Public Hygiene. Dr. A. Simard, of Quebec City, dealing with infant mortality, said that at least 2000 babes could be saved from death in that province with better care, proper sanitation, and hygiene. The conference also advocated the proper medical inspection and supervision of school children in all the elementary schools of the province.

Public Health Legislation in the Province of Quebec.

The Provincial Board of Health of the Province of Quebec was first organised in 1887, Dr. Lachapelle, of Montreal, being appointed president, and Dr. Pelletier, of Quebec City, secretary. After 26 years these two officers still continue in control of health matters in that province and to them is due the credit of the excellent Public Health Acts now in force. The board consists of nine members, four of whom must be physicians. In 1910 it was decided to divide the province into ten health districts, and six of these districts have since been organised with medical men in charge located in each district. All medical inspectors are required to hold a diploma of public health and to pass an examination prescribed by the Board of Health. Special attention is given to small-pox—always a menace throughout that province—and the Vaccination Act provides for vaccination in the first year after birth, and revaccination both in the eleventh and twenty-first years. During the present year in Montreal there have been 222 cases of small-pox—March heading the list with 51—and 1204 cases of tuberculosis—967 pulmonary and 237 of other forms.

Insanity in Quebec and Ontario.

In the Province of Quebec the care of the insane is under somewhat peculiar conditions, being entrusted to corporate bodies, religious or otherwise, by the Government, which makes a per capita grant for the public patients, who are allotted to the different institutions as follows: St. Jean de Dieu, 2000; Quebec Hospital for the Insane, 1257; Verdun Protestant Hospital, 515; St. Ferdinand Hospital, 145; St. Anne Hospital, 123—a total of 4040 public patients. Only Verdun makes returns of its private patients, and these number practically the same as the public patients. If the ratio in others is the same the officially insane in that province would approximate 8000. The amount paid by the Government for the public patients is $460,738.36. For the Roman Catholic institutions this is $112 per capita, while for the Verdun patients it is $142. Quebec has a total population of 2,000,000.

In Ontario for the last official year the total number of insane in the provincial institutions was 5726, 2769 being males and the rest females, a net increase of 86 for the year. The admissions for the year totalled 1247, an increase of 103; the deaths, 460, an increase of 45; and the discharges, 570, an increase of 28. The number of deportations was 258, an increase of 32, 66 being insane, 49 criminal, and 48 likely to become a charge upon the province. Manual and health work has been found most beneficial in lessening mental degeneracy, and a high standard of efficiency has been reached in the various institutions. The growth of insanity in the province is seen in the following statistics: 1882 to 1886, total 2775; in 1891, 3201; 1895, 3865; 1901, 4604; 1906, 4933; 1912, 5517. Of the 1247 admitted in the past year 890 inherited a predisposition. Of the admissions of the year 653 were men and 594 women, of whom 543 were single, 587 married, 116 widowed, and 1 divorced.

Dominion Medical Council Matters.

At the first examinations of the Dominion Medical Council held in Montreal on Sept. 7th some 66 candidates presented themselves. At the recent annual meeting the Ontario Medical Council instructed its registrar to accept Dominion registration as full qualification for licence in Ontario, subject only to the production of the necessary credentials and payment of the usual fee. Four provinces have now established reciprocity with Great Britain—namely, Quebec, Prince Edward Island, Nova Scotia, and New Brunswick. Only one province, British Columbia, has failed to comply with all the requirements of the Dominion Act. It retains the right to examine candidates for subsequent licence in that province in the final branches.

Sept. 23rd.

NOTES FROM SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Immigration Regulations.

A SERIES of regulations has recently been promulgated under the Union Immigration Act passed last session. Under these regulations the port health officer or other duly appointed medical practitioner is to be present at the examination of passengers by the immigration officer and to indicate any passenger whom he deems it necessary to examine medically before he is passed as an immigrant. Leprosy, trachoma, favus, framboesia, syphilis, and scabies are declared loathsome diseases, bringing those suffering therefrom under the category of prohibited immigrants. The regulations provide that persons suffering from tuberculosis may be allowed to land under a permit from the immigration officer, but these permits are only to be issued at the ports of Cape Town and Durban, and on the following conditions. The place of residence and the mode of transport thereto to be subject to the approval of the immigration officer, the immigrant to report himself to the local health authority at his place of residence, and to present himself for examination by the district surgeon or other approved medical practitioner whenever required; sleeping accommodation never to be shared with any other person, and regulations by the local health authority for preventing infection to others to be observed. It is clearly the policy of the Government to discourage the entry into the Union of tuberculous persons, although very little is being done to prevent the spread of the disease in the subcontinent itself. But with no properly organised health department the regulations are likely to be applied improperly or to become a dead letter.

Reorganisation of Hospital Work in the Cape Peninsula.

The Cape Hospital Board has appointed a committee of inquiry to advise as to the requirements of the Cape Peninsula and the reorganisation of work under the new *régime*. The committee having sought the advice of the Cape of Good Hope (Western) Branch of the British Medical Association, the Association approved the formation of a clinical medical school, but as that would require some years of preparation it recommended that the board keep steadily in view the provision of a large hospital for the university medical faculty. It recommended the early establishment of a pathological department under the control of a university medical faculty, and considered it desirable that the New Somerset Hospital should be entirely reserved for free patients with a view to its development into a teaching hospital, though the site of that hospital is hardly ideal, not being in the neighbourhood of the medical school. It recommended that the honorary staff should be specialised and the principle gradually introduced of requiring the staff to restrict themselves in private practice to their specialty. Also that, when a complete medical course was established, beds should be reserved for the university professors, and that in the meantime all holders of appointments as honorary visiting medical officers be selected by a mixed committee representing the lay board, the honorary staff, and the outside profession. It further recommended that free out-patients be treated at both the New Somerset Hospital and the Free Dispensary by an honorary out-patient staff appointed for the purpose; that the four suburban hospitals should, as at present, be conducted on the lines of cottage hospitals; that maternity blocks should be attached to the teaching hospital; and that an entirely new hospital on the small ward system should be built in as central a position as possible for contributing patients. Finally, it stated emphatically the opinion that it was unnecessary for the board to make provision for fully paying patients.

South African District Surgeons' Association.

At a meeting of the district surgeons representing all provinces of the Union recently held at East London, on the suggestion of the Transvaal District Surgeons' Association it was unanimously agreed to form a South African District Surgeons' Association, with a local committee in each province. The following provisional committee was appointed: Dr. Grinsell (Stutterheim) and Dr. E. G. Dru Drury (Grahamstown), representing the Cape Province; Dr. D. Campbell Watt (Pietermaritzburg) and Dr. J. Dodd (Ixopo), representing Natal; Dr. Moorhead (Rustenburg) and Dr. Nixon (Heidelberg) representing the Transvaal; and Dr. D. M. Tomory (Bloemfontein) and Dr. P. D. Strachan (Philippolis), representing the Orange Free State. Dr. Campbell Watt was unanimously elected the first president and Dr. Moorhead vice-president, and Mr. W. A. J. Cameron, of Johannesburg, a temporary secretary. The rectification of the grievances of district surgeons under the existing regulations, and the contemplated promulgating of new regulations curtailing many of the existing fees, were the determining causes of the new association.

Railway Sick Fund Regulations.

The long awaited new [illegible] of the Railway Sick Fund [illegible] The control of the fund [illegible] board of 16 members, half to be nominated by the administration and half elected by contributors. No provision is made for medical representation, although it is possible that the administration may intend to nominate one or two medical men as their representatives. Subordinate to the board are to be four district boards with offices respectively at Cape Town, Bloemfontein, Johannesburg, and Durban. On these also there is no specific provision for medical representation. The objections to the regulations are very numerous. The new regulations are understood to have been compiled without reference to contributors to the fund, to the medical men concerned, or to the medical profession. It is of the utmost importance to the railway employees that their medical service should be an efficient one. The medical officer has hard work to do his duty both to the railway administration and to the patient. It is utterly impracticable for laymen unassisted by professional advice to draw up satisfactory regulations; yet this is what the railway administration has endeavoured to do. The new regulations are perhaps objected to more strongly in Natal than elsewhere. At a meeting of the [illegible]

[illegible] stated that he had been offered the appointment as railway medical officer to the Greyville district. There were 2380 (estimated) railway workers in this district, including wives and children of the actual employees. He was offered £500 per annum. A few extras were allowed, the chief being £2 2*s.* for midwifery cases and £1 1*s.* for anæsthetics and for consultations; also a travelling allowance of 8*d.* per hour [illegible] duty. He had worked out the [illegible] estimate of the incidence of sickness would be 3 per cent., giving about 60 attendances per diem. This was more than one man could manage, and if an assistant and two motor-cars were kept it would all have to come out of the £500 per annum. Dr. Howden further pointed out that the majority of these people had previously been private patients, so that practices would be broken up and for ridiculously low rates of payment. He might well also have added that in addition there would be interminable correspondence connected with such a post. From the general discussion it was evidently the consensus of opinion that the terms were totally inadequate and should be strenuously resisted. Eventually resolutions were agreed to calling for conference with other branches as to their attitude, standing by the 12*s.* minimum rate for adult workers and adopting the principle of free choice of doctor, and informing the Central Board that members of the branch would not be allowed to negotiate individually for the posts of railway medical officer until terms were accepted by the branch and inviting a conference between the board and the branch. Dr. Howden, Mr. S. Copley, Mr. B. A. Nicol, Dr. A. McKenzie, and Dr. Duncan McKenzie were appointed a committee to deal with the matter and, if necessary, to meet a delegation from the sick fund and to report to the branch. The firm stand taken up by the Durban practitioners is very satisfactory.

Sept. 5th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Medical Research in India.

THE first number of the new Indian *Journal of Medical Research*, edited by the Director-General of the Indian Medical Service and the Sanitary Commissioner with the Government of India, is now under issue as a quarterly. It is published for the Indian Research Fund Association and takes the place of the Scientific Memoirs. Sir Harcourt Butler in a foreword says: "The time has come for the fund to have its own official organ, and the *Journal* should be a worthy record of what is being done in India for the advance of sanitary science in the widest sense of the term." Its pages will be open to all, official and non-official alike, for papers on subjects of research connected with medical and sanitary science. It is added that research work is rapidly developing in India, and Sir Harcourt Butler makes an earnest appeal to all who are interested in it to support the journal and enable it to hold a high place among the scientific journals of the world. The first number contains 16 articles dealing, amongst other things, with cholera, kala-azar, dysentery, latent malaria, &c. Photographic reproductions of certain biting insects are beautifully done. The journal, which is published by Messrs. Thacker, Spink, and Co., of Calcutta, is admirably printed on thick paper. Its price is six rupees per annum.

Hospital Accommodation in Cochin.

The Anglo-Indian community of Cochin, numbering over 3000, are making arrangements to memorialise the Madras Goverment, through the local municipal chairman, to reconsider its decision to omit the proposed European and Eurasian ward from the estimate of the new Municipal Hospital submitted by the local civil surgeon.

Infant Mortality in Bengal.

In the annual report of the Sanitary Commissioner for 1912, just published, it is stated that nearly 340,000 children under one year died in Bengal, representing a loss of 21 per cent. of the births. The figures for 1911 were just under 310,000. Calcutta has hitherto returned the highest infant death-rate—26 per cent. of births—but Jalpaiguri, with 28·69 per cent., and Dinajpur, with 26·26, are now worse. Cholera and fever have been prevalent, but infant mortality is not largely due to these diseases, but to ignorance of hygiene and want of skilled medical treatment.

Child Life in Calcutta.

A correspondent of a Calcutta paper draws attention to the fact that little children are employed in the city to descend the drains and clean them. The corporation should take the matter up and substitute more humane and up-to-date methods of cleaning the drains of the city.

The Drainage of Imperial Delhi.

The scheme for the training of the Jumna at Delhi is to be prepared in due course. Th[illegible] likely to be great, and with [illegible] in river training in India t[illegible] two or three years. When once the Jumna has been "trained" it can be kept to channels that will leave the area now liable to flooding high and dry all the year round.

Ambulance Work in India.

General Haji Hafiz Obeidullah Khan, C.S.I., Imperial Service Lancers, has signified his intention of presenting an ambulance challenge shield to the Indian Council of the St. John Ambulance Association for competition among the units of the St. John Ambulance Brigade in India and Burma.

Tube Wells in India.

Experiments with tube wells in India are still being carried out, and experience alone can show where they can be used with full advantage, but of their utility in some tracts there can be no question. In Vol. II. of the proceedings of the All-India Sanitary Conference at Madras a short paper by Mr. T. A. Miller Brownlie, municipal engineer of Amritsar, gives some particulars of borings and workings. His concluding paragraph is worth particular attention, for he says: "The question of the relative cost of tube wells is of no great importance when one considers that from an ordinary masonry well 12 feet in diameter, as built for modern water-supplies, the average yield is roughly 3000 gallons per hour and the cost is over £200; whereas at a less cost a tube well can be sunk which will yield 45,000 gallons per hour, or 15 times the supply of an ordinary well and under the same head." After such a statement we can fully agree with him that a considerable amount of good can be done by the installation of tube well water supplies for towns and villages of India which are in urgent need of pure water. It is to be hoped that experiments will be steadily continued and that the results gained will be made public.

Town Planning in India.

The Government of Madras has now taken steps to frame a set of rules, and has issued them for the guidance of municipal councils, to ensure that schemes for the extension of sites and the provision of house accommodation are carried out with regard to sanitary principles. Certain draft rules were first circulated amongst the various municipalities in the Presidency for their criticism. A large majority of the municipalities approved of the rules in their entirety, while several of them, like Coimbatore, Ellore, and Tanjore, made some excellent suggestions based on their own experience. The rules come into force on Oct. 1st in all except hill municipalities. All such undertakings have to receive the approval of the district medical and sanitary officer or the Sanitary Commissioner, with special reference to the suitability of the soil for building construction, facilities for drainage, water-supply, and other matters. Streets are required to be marked out on the sites, and as far as possible to run in straight lines crossing one another at right angles, and the main streets, exclusive of lateral drains, are to be not less than 40 feet, the secondary streets not less than 30 feet in width. All streets are to be metalled throughout their entire width, not merely in the centre of the roadway, and any departure from this rule is to be made only with the sanction of the Government. Conservancy lanes 10 feet in width, exclusive of lateral drains, must be formed along the backs of houses, and streets must be provided on both sides with open and impervious unshaped drains to carry off storm-water. The formation of streets and drains, it is wisely laid down, should form part of the scheme for laying out the sites, and should ordinarily be put in hand simultaneously with the execution of the scheme. In large streets the municipality will maintain suitable avenue trees on both sides of the street.

Efficient Medical Women.

The results of the examinations of the Agra Medical College seem to show that the women students are more efficient and more diligent than the men. Major E. J. O'Meara, I.M.S., in his annual report, states that 65 male students appeared at the final medical examination in April, 1913, and only 29 passed in all subjects. Out of 20 women students who presented themselves 13 passed in all subjects Of the male failures 27 were remanded for one year and 9 were recommended for dismissal, as in the opinion of the Medical Board they are never likely to pass, and their retention is a waste of money to the Government.

Pasteur Institute for Burma.

In sanctioning the scheme for a Pasteur Institute in Burma the Secretary of State has been pleased to sanction the proposal put forward by the local Government that the balance of the grant of two lakhs by the Government of India for the purpose of erecting a bacteriological institute at Maymyo, part of which has already been devoted to the construction of a combined chemical and bacteriological laboratory at Rangoon, shall be applied to the provision of a small bacteriological and serological laboratory in connexion with the Pasteur Institute at Rangoon and the construction of quarters for the director.

Sept. 20th.

Obituary.

WILLIAM CARNEGIE BROWN, M.D., C.M. ABERD., M.R.C.P. LOND.,

PAST SECRETARY OF THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

THE death of Dr. W. Carnegie Brown has removed one who had done much to draw together the groups of individuals interested in the study of tropical medicine, owing to the important part which he took in the formation and development of the Society of Tropical Medicine and Hygiene, and at his funeral on Oct. 2nd the society was represented by Sir Ronald Ross, past president of the society; Dr. F. M. Sandwith, vice-president; Dr. T. P. Beddoes, and Dr. C. F. Harford, one of the present honorary secretaries. Dr. Sandwith also represented the London School of Tropical Medicine, and a wreath was sent by Sir Patrick Manson, the first president of the society.

William Carnegie Brown received his medical education mainly at Aberdeen, though he also studied at St. Thomas's Hospital. He took his M.B., C.M. Aberdeen in 1880, and after that saw something of life abroad by serving as medical officer of the White Star and P. and O. lines. In 1884 he took his M.D. degree, and from 1885 onwards he was medical practitioner in Penang, in the Straits Settlements. Here he gained good insight into tropical diseases, and, being a careful observer, made a study of some of the principal diseases that are met with in that part of the world. His chief contributions to the literature of tropical medicine, published since his return home, have been two books, one on "Sprue and its Treatment," which was published in 1908, and the other on "Amœbic Dysentery, its Complications and Treatment," published in 1910. Both of these books give a very good summary of the knowledge available concerning these two diseases at the time of writing, and it will be admitted that both these subjects are worthy of a good deal more consideration than has been generally accorded to them.

In the year 1904 he returned to England and took rooms in Harley-street, and at once associated himself with workers in tropical medicine. In 1906 he became a Member of the Royal College of Physicians of London, and in 1907, when a movement was started to found a new Society for the Study of Tropical Diseases, Dr. Carnegie Brown was chosen with Dr. Sandwith to be one of the honorary secretaries. By his tact and hard work he contributed largely to the success of the new society and gained the confidence of all his colleagues, and he continued to hold the post of secretary of the society until his health failed in the summer of 1912, when he felt obliged to resign his office. As a matter of fact, for some time previously he had been failing in health, but he stuck to his post with the greatest zeal, even though he did so at great cost to himself. The fact that there are at the present time 608 Fellows of the new society, although it has only been in existence six years, is the best monument to the indefatigable labours of Dr. Carnegie Brown. Many difficult questions came up for consideration by the society during his term of office, and nothing exercised him more keenly than the negotiations which took place between the Royal Society of Medicine and the Society of Tropical Medicine and Hygiene on the possibility of amalgamation. Dr. Carnegie Brown felt most keenly the seriousness of the problem, and he was of opinion that the cause of tropical medicine, represented as it was by medical men scattered throughout the world, needed a special society to represent its interests. He was not identified with any of the teaching schools, and therefore he could act in a specially disinterested manner, and this fact lent great value to his services. His good judgment in arranging the programme of the session and in securing papers from those best qualified to deal with particular subjects was most noticeable, and he has left behind him a record of patient and persevering work which cannot fail to act as a stimulus to his old colleagues and to all who remember him.

Dr. Carnegie Brown leaves a widow, three sons, and three daughters.

DAVID MOUNT HUTTON, B.Sc., M.D., C.M. EDIN.

BORN in Liverpool of Scottish parents 43 years ago, David Mount Hutton received his primary education at preparatory schools in St. Andrews and Edinburgh, and with a sound equipment in literature, classical, English, and German began professional study at the Edinburgh University, first in science, in which he graduated B.Sc. in 1892, and thereafter in medicine proper, taking the M.B. and C.M. degrees in 1895, and finally the "summi in medicina honores" with honours in 1899.

So qualified, he entered immediately on general practice at Southport-cum-Birkdale and rapidly acquired the confidence of a large *clientèle*, thanks to the very thorough clinical training he had undergone as resident physician in the Edinburgh Infirmary, and also as physician in the Royal Children's Hospital in the same school. In quick succession he became medical referee to the Scottish Provident among other insurance companies, Fellow of the Royal Society of Medicine, and an active member of the North of England Obstetrical and Gynæcological Association, as also of the Society for the Study of Children's Diseases. Latterly, amid much strenuous professional work, he interested himself in the movement, now progressing under Government auspices, for the Care of the Feeble-minded, aiding it effectively on the platform and in the press, while acting as President of the Southport Branch of the Lancashire and Cheshire Society organised in the same philanthropic interest. He even found time for enriching the literature of the profession by articles such as that on Myiasis, published in the "Encyclopædia of Medicine"; on a Case of Syphilis Transmitted to the Third Generation, printed in the Transactions of the Society for the Study of Children's Diseases; on [illegible] paper published in the "Special Schools Quarterly."

Fifteen years of such work, rarely and never adequately relieved by respite or holiday, began, however, to tell on a constitution in the main robust, but not proof against the handicap of an anxious temperament and a sense of duty that never spared itself. Premature breakdown became more than ominous, insomuch that preparations were on foot for a six months' *villeggiatura* in Italy. But—*Dis aliter visum*. The project indeed had barely been initiated under a medical friend's roof near London, when suddenly, if not quite unexpectedly, he succumbed to heart failure on Sept. 21st. "And so," writes a valued correspondent of THE LANCET who knew Dr. Hutton intimately, "there 'went down while it was yet day' the 'sun' of a guileless and generous nature which, devoted—mind and soul—to the medical calling, 'knew its art but not its trade,' finding its true honorarium in the gratitude it earned not only by the skill acquired in the schools but by the *sagacité de cœur*, which is the precious, the distinctive possession of the born physician."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. A. van der Loeff, formerly inspector of the medical service in West North Brabant and Zeeland, aged 71.—Dr. P. Alt, privy sanitary councillor of Charlottenburg.—Dr. F. Deus, sanitary councillor of Berlin.—Dr. A. Pitschpatsch, sanitary councillor of Sagan.—Dr. A. Thorwith, sanitary councillor of Berlin.—Dr. Julius Preuss, of Berlin, whose contributions to the press on the subject of Jewish medicine in history are of great and universal interest. His latest work, which includes most of his previous researches, was "Biblisch-talmudische Medizin." His age was 52, and he held the rank of sanitary councillor.—Dr. Theodore S. E. Schaepkens van Riempst, lecturer on genito-urinary diseases in the New York Polyclinic Medical School and Hospital.—Dr. John P. Pardue, formerly professor of materia medica and hygiene in the St Louis College of Physicians and Surgeons.—Professor Robert Kutner, director of the Kaiserin Friedrich Haus, Berlin, and general secretary of the International Committee for Post graduate Medical Education.

Correspondence.

"Audi alteram partem."

THE PATHOLOGY OF THE CONDITION KNOWN AS PARASYPHILIS.

To the Editor of THE LANCET.

SIR,—The extremely interesting and highly scientific paper by Dr. J. McIntosh and Dr. P. Fildes in THE LANCET of Sept. 27th tempts me to write a brief note on the subject as it presents itself to one who has had a certain amount of clinical experience and training, but very little experience of, or training in, modern precise methods of microscopical and biochemical research.

I would first mention three small items of great interest to myself, and of what I *consider great clinical importance*. The first one is a statement made by the late Sir Jonathan Hutchinson when teaching a class of students of whom I was one. He said that he had watched a patient for many years whose sole indication of tabes dorsalis when first seen was the absence of knee-jerks. He had, in the course of time, developed the other classical features and had ultimately died from progressive nerve trouble. I had then, and have not now, any reason to doubt his statement.

The second item is a fragment of a conversation I held some seven or eight years ago with my late colleague, Harold Barnard, who said to me, "Smith, what is your rule and teaching about administering mercury to patients suffering from disease and whom you suspect to have had syphilis at some previous period upon which the present symptoms may possibly depend?" I replied very promptly, "I teach and practise that in all such cases mercury should be very freely and promptly administered, and that iodides might also be given, but mercury never under any circumstances omitted." "How do you give mercury?" he asked, and my reply was, "Invariably by inunction of the ung. hydrarg. of the B.P." I have seen no reason to depart from my teaching or to alter my rule.

The third item is a case from my private practice. In November, 1895, I was asked by Dr. J. J. Coulton to see a patient then aged 33, who had acquired syphilis "in the *year of the Paris Exhibition." (So my note runs. I have no* reference by me to fix what this year was.) Subsequently, he had suffered from gumma of the testicle, but "all seems to have cleared up," and he was well till three days previous to my first consultation, when he was suddenly seized with aphasia and amnesia, could not write at all properly, began words and could not finish them, used wrong words, &c.; these symptoms had improved under K.I., with which his medical man had treated him. I have a few more notes on his nervous system, but they are not very material. I heard in March, 1896, that he had got quite well after three months of *mercurial treatment* combined with potass iod. In October, 1897—i.e., nearly two years later—I saw him again with some acute illness which at [illegible] fever, but as he had some [illegible] *speech, mind far from clear,* [illegible] accounted for by typhoid fever, I ordered ung. hydrarg. to be rubbed in. I saw him again a fortnight later, and my note runs: "No doubt now about G.P.I. He has been made [illegible] "His lips and speech are very [illegible] and his knee-jerks are greatly [illegible] react steadily to L. and A." By [illegible] and in mind. K.J. ++. Pupils react fairly, but not absolutely as they ought to do. In 1898 he came to me to ask advice as to the frequency with which he ought to indulge in sexual connexion; desire and power both in excess. In 1899 my note runs: "Feels very well. Hands quite steady; mentally clear; good head for business. K.J. natural and equal; pupils react readily to L.; tongue quite steady." In 1901: "A bit below par. K.J. slightly glib. Pupils react readily to L. and A." In 1906: "Health excellent. K.J. both fairly free." I have not seen the patient since then, so that he may have died in the interval, and that, too, from G.P.I.

I leave these items for a moment to mention the views that I adopted in my student days and taught when I reached a position of responsibility to students and still teach—viz., that if parasyphilitic had any meaning at all it was intended to convey the idea that active syphilisation had ceased, but before ceasing had produced such disturbing effects upon lymph- and blood-vessels as to diminish the food-supply to, and removal of waste products from, the nerve fibres or cells to such an extent that the cells, and therefore the fibrils dependent on the cells, slowly but surely, and usually progressively, perished. All this seemed to me a legitimate deduction from what was then known of the power of syphilis to produce what was termed syphilitic endarteritis—a process that resulted in diminishing the calibre of the vessel below its optimum. I had then no suspicion that the microbe of syphilis could still be alive, and could be continuing to produce toxins having a primary deleterious action upon nerve cells.

It would make my comments too long to pass in review, as Dr. McIntosh and Dr. Fildes have so ably done, the various stages in the controversy regarding parasyphilis, but I would like to contradict flatly, by my own experience, the statement that "the result of treatment is *nil.*" Your authors dispute the statement, and my experience confirms their view, but there must, of course, be added the proviso that treatment by mercury must be undertaken early, and often, indeed, while the evidence of syphilis is still doubtful. (I do not wish here to enter upon the value and importance of the Wassermann reaction, because I hold the view that mercury is useful in other conditions than syphilis, and therefore treatment can do no harm and may be of immense good even if syphilis be not a factor in the trouble.)

I would like to ask Dr. McIntosh and Dr. Fildes for a critical consideration of my case mentioned above; to call it a "particularly toxic secondary encephalitis," and to refuse it the name of "early general paralysis" seems to be somewhat of an anomaly.

I would like, Sir, in conclusion, to ask them also whether I am correct in saying that the most elaborate investigations of modern research do not contradict in any essential particular my view of what one ought to teach students. By essential I mean affecting the chances of the patient's cure. Or would they urge me to wait for the results of a Wassermann before resorting to mercury? (I do not wish to enter into any controversy as to the relative merits of mercury and neosalvarsan for the cases I am considering.) It seems to me that modern pathology rather supplies a firm basis of ascertained facts for my practice, a position of affairs which naturally gives me great satisfaction; and I shall conclude that it is never, clinically speaking, too late to apply antisyphilitic treatment.

I am, Sir, yours faithfully,
F. J. SMITH, M.D.Oxon.,
Physician to the London Hospital.
Harley-street, W., Oct. 2nd, 1913.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 27th you printed a contribution from us entitled "The Pathology of the Condition known as Parasyphilis." In this paper we put forward the view that dementia paralytica was merely the expression of tertiary syphilis of the brain. The condition differed from the gummatous processes confined more or less to the lymph vascular tissues, in involving chiefly or entirely the nervous substance proper. The wide extent of the lesion resulting from a minimal number of spirochætæ was due to the fact that the patient was in a "tertiary" condition—in other words, because his tissues were hyperimmune (hyperallergic) to the virus. Acute encephalitis was a lesion pathologically similar, but since its onset was relatively early after infection the tissues had not become hyperimmune, and thus a marked spirochætosis produced relatively little reaction and destruction.

We wish now to mention that Professor Noguchi, in the current number of *La Presse Médicale* (Oct. 4th), demonstrates that normal rabbits are insusceptible to intracerebral inoculations of spirochæta pallida. If, however, the animal is sensitised by repeated intravenous injections of spirochæta pallida, an intracerebral inoculation will then produce the lesion of dementia paralytica. Noguchi's investigations appear to supply the experimental evidence which is at present lacking in our purely inferential study.

We are, Sir, yours faithfully,
JAMES MCINTOSH.
PAUL FILDES.
London Hospital, Oct. 6th, 1913.

THE NATIONAL INSURANCE ACT: THE APPOINTMENT OF MEDICAL REFEREES.

To the Editor of THE LANCET.

SIR,—Medical men of all ranks are frequently asked by insurance offices or employers to examine claimants who allege that they are suffering from either accident or disease, and it is one of the settled ethical laws which govern the profession that, knowingly, no medical man shall examine the patient of another medical man except in consultation or after having first obtained his consent.

House surgeons and general practitioners continually meet medical examiners acting for insurance offices, but they decline to do so unless they are paid the usual consultation fee of £1 1*s.* The most recently qualified house surgeon will decline to attend a consultation or to write a report under the fee of £1 1*s.* General practitioners all over the country receive the same fee, if not more, for their loss of time, care, and responsibility, when called upon to give at a consultation a detailed history of a case. The Home Secretary, in fixing the fees of medical referees under the Workmen's Compensation Act, fixed a fee of £2 2*s.* as the fee for a medical examination and report to a county court judge, and no one has ever hinted that this sum is excessive.

Bearing in mind the above facts, the question arises as to what should be the attitude of the profession in regard to the appointments of medical referees by Local Insurance Committees, either at small salaries or at fees hitherto unheard of for the class of work required and without any published regulations safeguarding the ethics of the profession.

The London Insurance Committee have appointed six medical referees for the county of London, and these practitioners have presumably agreed to make visits, hold consultations with panel doctors, and write reports for the information of the Insurance Committee at an inclusive fee of 7*s.* 6*d.* per case, on which reports the standing, knowledge, and experience of the panel doctor are to be adjudicated on by the committee, as is also the character of the insured persons whose *bona fides* is in question. These latter persons will be at the mercy of an Insurance Committee solely dependent for its information on the report of a medical referee, and they may be branded as malingerers or exaggerators by the committee in a manner which may affect their whole future lives.

Six medical practitioners have accepted this enormous responsibility at a remuneration of 7*s.* 6*d.* for each consultation, examination, and full report, and it seems most improbable that any of these gentlemen, who have accepted these appointments, have realised their onerous and responsible nature or the time that must be given to each report if justice is to be done to the parties interested, or that they have satisfied themselves that regulations have been made for the obtaining in each case from the panel doctor in charge a full and exhaustive history at a consultation to be attended by the panel doctor, on terms satisfactory to himself and the profession.

If such regulations have been made the profession has a right to ask that they may be published in the medical press, so that every medical man on a panel may know exactly how he stands under the regulations, having regard to the ethics of the profession. It may be that medical referees appointed by the Insurance Committee are merely intended to advise in the first instance on a short form, but even if so, and if there is to be a right of appeal either to the Insurance Commissioners or to medical referees appointed by the Commissioners under the powers they hold under the National Insurance Act, yet even then it is most essential that the reports of medical referees to the Local Insurance Committee should be thoroughly well considered and written under a due sense of responsibility. It is generally understood that after the report of the Departmental Committee now sitting the whole question of medical referees, both under the National Insurance Act and the Workmen's Compensation Act, will be carefully considered, and no doubt the following three questions will be kept in view: (1) Whether the decisions of medical referees shall be as now, "final and conclusive," or whether they shall be subject to appeal; (2) whether they shall be whole-time officers or part-time, payable by fees, as at present; and (3) whether a simplification of procedure and a saving of expense could not be effected by the appointment of one body of medical referees to examine and report under both the Workmen's Compensation Act and the National Insurance Act.

It will be generally felt that with a more extended use of medical referees, especially if their decisions are to be "final and conclusive" and if they are to have the confidence of the profession, they should be men of ripe experience, not only in the various kinds of medical practice, but especially in the examination of persons claiming to be incapacitated by either accident or disease, and that they should be men of tact, well used to meeting every kind of medical practitioner in consultation.

I am, Sir, yours faithfully,

South Hampstead, N.W., Oct 4th, 1913. ALBERT BENTHALL.

THE DISCOVERY OF THE RADIUM-MESOTHORIUM CURE OF CHRONIC DEAFNESS OF THE HOPELESS KIND.

To the Editor of THE LANCET.

SIR,—Among the seriously inaccurate statements that have quite recently been made in the lay press in regard to treatment by radium and radio-active agencies that alleged to have emanated from the "Medezenalen Klinik" in which Dr. Hugel, of Berlin, is credited with having discovered the curative effects of radium and mesothorium in chronic deafness, is one that cannot be allowed to pass unchallenged.

Having in October, 1908, observed and realised the curative effect of what I had provisionally termed the "ultra-X rays" in a cast of chronic deafness in a hospital out-patient, who was being treated under my directions for specific gummata of the tongue, obliquely through the open mouth, a second case that had been otologically examined and given up as hopeless, being that of an acquired deaf-mute, was experimentally subjected to a similar course of "ultra-X ray" treatment with very satisfactory results. Both cases were subsequently exhibited at the hospital clinical meetings, and were duly published.

As two such exceptional experiences were not sufficiently conclusive they were subjected to the test of time, and the experiments were repeated in a few similarly hopeless deaf cases in 1909. During this year I also began to treat some with a plaque of radium bromide which I fixed over the mastoid process, and later the radio-active mineral autunite was introduced into the meatus in 1 centigramme metal capsules. In April, 1910, I brought forward two of the originally deaf patients before the Neurological Section of the Royal Society of Medicine, in order to illustrate what I then termed the neurogenetic effect or amœboidism induced by these radiations in nerve terminals. Owing to the large number of cases that were exhibited on that occasion the exhibition of mine was unavoidably deferred.

This experimental research was, however, continued without intermission in spite of the *obstacles* that presented themselves. By August, 1912, having had a large and convincing experience, I submitted the notes of a few of these cases to THE LANCET. The Editor courteously replied in returning my notes, and suggested that my cases had better be exhibited and discussed at one of the medical societies before *publication. Accordingly, in* November, 1912, *the notes* of my eight earliest cases (five of which were originally deaf-mutes) were submitted to the president of the Otological Section of the Royal Society of Medicine. After a few days he expressed his interest in the notes and kindly offered to introduce me to the meeting when the time arrived. Not being an otologist or a member of that section, I was informed that the notes would first have the consideration of the council before a date could be fixed for their discussion. This date was finally fixed for Feb. 21st, 1913, three months later.

At the eleventh hour, however, after the circulation of the notes on the agenda paper of the meeting, certain of the members of that section raised a protest to the president, threatening to resign and form another otological society if my cases were examined or discussed. The president, under these circumstances, reluctantly complied with their demands, and I was requested to cancel by wire my invitations to my patients, but this I could not bring myself to do; the patients were there, also a few medical men concerned in them, but they were not examined or discussed, to the consternation of many. I had the honour, however, of introducing some to the president.

Since this incident in the research that matter has been in the hands of my legal advisers. The experiments were continued, and in June last, at the invitation of the British Oto-laryngological Society, I was able to exhibit four further cases that had been otologically tested both before and after a four months' course of treatment. A report was published in THE LANCET of July 26th last at p. 223, which speaks for itself. For this kind aid I desire to thank the Fellows of this society.

As the identical relationship of the radiations emanating from radium and mesothorium with those from such a Crookes's tube to the discharges from which I have provisionally applied the term "ultra-X" to may be questioned by some practitioners, permit me to describe that association briefly. Radium and mesothorium are elements both of which discharge the long beta and the gamma radiations, the "surpenetrans" of Dominici, but the enclosing metal or filter that is used to cut off the inevitable short radiations that damage the skin structures has, set up within the molecules of the metal, new secondary radiations of short length, the action of which has also to be provided against by more dense covering, other factors need not here be mentioned. A Crookes's tube that becomes useless for superficial therapeutic purposes, after repeated regenerations, the vacuum being now very high, it ceases to discharge the short radiations, though the long beta and gamma radiations continue to be discharged for some time longer with proper management, while using a heavy current and a spark-gap of from 10 to 12 inches. At this stage there is no difference therapeutically between these types of radiations from the sources under consideration. There is no primary necessity for protecting the skin from the action of these ultra-X rays. No metal filter being applied to the skin, *there are no secondary* radiations generated at the skin. An aluminium filter or thick leather disc is used in the path of the rays, at some distance from the skin surface, as a precaution against the occasional softening of the tube by heat at the anode when the cooling device fails. This valuable deep therapeutic feature of a high Crookes tube has not been known to medical science hitherto.

I am anxious to invite discussion which may help us nearer to the truth which we are all seeking.

I am, Sir, yours faithfully,

Gloucester-place, W., Oct. 7th, 1913. H. D. McCULLOCH.

AURICULAR FLUTTER.

To the Editor of THE LANCET.

SIR,—I have read with much interest Dr. J. Hay's narrative of two cases of auricular flutter in your issue of Oct. 4th, but my object in writing you on this occasion is not to offer any comment on the suggestions it contains either as to the nature *or treatment* of that condition. To do so satisfactorily would require more space than you might feel disposed to grant and involve discussion more suited to a longer article. The subject, however, *is one of increasing* interest, and a considerable number of cases of the condition in question have now been observed—30 in all, according to Dr. W. T. Ritchie in his valuable article just published in the *Quarterly Journal of Medicine.* For personal reasons I have some reluctance in troubling you even with the note I am about to write, but statements of fact, however pardonably erroneous, are apt to become stereotyped if left uncorrected.

The first case of non-drug auricular tachycardia recorded was one mentioned by myself in an address given in October, 1908, and published in THE LANCET of Jan. 9th, 1909. It was under my care in the Great Northern Central Hospital in 1903, and was associated with audibility of the extra auricular systoles as well as with their reproducibility by the graphic method.

Dr. Ritchie recorded a high rate of auricular pulsation still earlier[1] in a case of ventricular bradycardia, but the auricular speed in that case followed the administration of atropin, and he refers in his last paper to another case published by the late Dr. G. A. Gibson. These observations were all made prior to those on the interesting and important case recorded by Dr. Hertz and Dr. Goodhart in January, 1909, not in 1908, as stated in Dr. Hay's paper.

Dr. Ritchie mentions that in his atropised case of accelerated auricle no auricular sounds were heard. The audibility of the sounds in my case, which I described to the Æsculapian Society on Dec 13th, 1908, as "jugular embryocardia,"[2] was probably owing to the comparatively slow rate of the massed rhythmic auricular extra systoles, as I consider them to be, in spontaneous cases and to their force. The auriculo-ventricular ratio was as 2 to 1. The higher the auricular rate and the more nearly the pulsations approach the impotence of auricular fibrillation, into which they may apparently at times pass, the less audible in all probability are the auricular sounds likely to be.

I am, Sir, yours faithfully,
ALEXANDER MORISON.
Upper Berkeley-street, W., Oct. 6th, 1913.

LOW-PRICED CLINICAL THERMOMETERS.

To the Editor of THE LANCET.

SIR,—The variations in the readings of the thermometers described by Dr. J. B. Cook in his letter in your issue of Oct. 4th are not necessarily indications of faulty instruments. It is possible to immerse a dozen quite reliable instruments in warm water and obtain as many different readings. In performing the test, among other precautions to be observed one should ascertain that the thermometers have been well "shaken down," that the water is maintained at a constant uniform temperature, and that the instruments do not touch the bottom or sides of the vessel. Of the many dozens of clinical thermometers examined here the percentage of rejections is very small indeed, and the greatest error observed has not exceeded one degree.

The price of 10*s.* 6*d.* per dozen cannot be described as cheap, for accurate 2 min. and ½ min. thermometers can be purchased from makers at far less than 10½*d.* each, while 1 min. thermometers fitted with a lens front and verified at Kew are obtainable at less than 2*s.* each. Dr. Cook does not state whether he ascertained the behaviour of the thermometers when used to take the temperature of the body.

I am, Sir, yours faithfully,
F. A. HOCKING,
Oct. 4th, 1913. Pharmaceutist to the London Hospital.

DISTRIBUTION OF INSURED PERSONS UNDER THE CAPITATION SYSTEM.

To the Editor of THE LANCET.

SIR,—In your report of the last meeting of the London Insurance Committee you mentioned that Mr. E. B. Turner rose to correct my statement as to the Manchester scheme. I have this morning received a letter from Dr. J. H. Taylor, of Salford, and with his permission I venture to ask you to print the following extracts from that letter :—

> I notice that according to the *B.M.J.* supplement, p. 286, Mr. Turner says you were in error about the Manchester scheme. As a matter of fact, it is he who is altogether wrong. We have a panel in Manchester and Salford in every sense of the word and as defined in Regulation 7. All the d [illegible] the Act and [illegible] ant, and the [illegible] the Local Medical Committees do not like the word panel, and so they use the word "list,' but it is a sort of *placebo* which they use with a nod and a wink.
>
> Again, Mr. Turner said that the Manchester Insurance Committee handed over the whole of the Medical Benefit Fund to the Local Medical Committee. If he meant exactly what he said it is another pious delusion like the first, which he may have heard in Manchester. Your own statement was far more correct than his. What really happens is as follows, and I speak with certainty here as a member of the Salford Insurance Committee appointed [illegible] The system in Manchester is a copy of the [illegible] neither case is a single farthing handed over to [illegible] mittee. The whole Medical Benefit Fund, tha [illegible] person (*less* a few contributions to persons receiving treatment through institutions and to persons making their own arrangements, who are very few in number), is divided up into three funds—13/17ths going to the panel fund, 3/17ths to the drug fund, and 1/17th to the drug suspense fund. To the panel fund is then added 6*d.* per person for domiciliary treatment of tuberculosis, which forms the medical treatment pool out of which the doctors are paid per attendance. The important point is that the whole of this pool is paid to the doctors, except that at each payment-on-account a very small sum has been kept in hand by the Insurance Committee, partly because a number of the doctors neglect to send in their accounts in time, and partly because it is impossible to tell beforehand the exact total for the year owing to the variation in the total number of the insured, and thus with [illegible] be kept in hand, but th [illegible] of the year the full t [illegible] was retained in hand on July 31st out of a total pool that will certainly be over £28,000 for the year. Practically, then, you were quite correct in saying that the whole fund available for medical treatment of the whole of the insured is paid to the doctors. Of course you know that the doctors have no lists as you have with your capitation system. We know nothing of the insured until they actually come to us for treatment, and they are allowed to go to any doctor, changing from one doctor to another as they like, Regulation 18 not being enforced. This, by the way, tends to increase the malingering, because if one doctor refuses a certificate the person simply goes about till he can find some other doctor ready to give a certificate. It is somewhat farcical for Mr. Turner to say that the money is handed over to the Local Medical Committee. All that committee does is to scrutinise the doctors' bills, and it has the power, which is often used, to cut down any doctor's bill when his attendances have been above the average, as excessive attendances would, of course, unfairly deplete the pool. When the bills have thus been checked they are sent to the clerk of the Insurance Committee, who again checks them to see that none but insured persons have been included, and the clerk then presents them to the Insurance Committee, which may pass them for payment. Of course, the Local Medical Committee has nothing to do with the drug fund. Up to the present the whole pool has only sufficed to pay the doctors about 60 per cent. of their bills charged according to a scale of fees agreed on between the Insurance Committee and the Local Medical Committee, but this small dividend is solely because of the large number of attendances, the insignificant sum kept in hand by the Insurance Committee making no practical difference. You will see that on our system we avoid your difficulty of unallotted funds, but we have what is to my mind a far worse difficulty—namely, that payment by attendance encourages each doctor to put in as many attendances as possible.

The matter is one of considerable importance, but Dr. Taylor has stated the case clearly, and I think no comment is needed to show that the misunderstanding as to the system of payment in Manchester was Mr. Turner's, not mine.

I am, Sir, yours faithfully,
Oct. 8th, 1913. H. H. MILLS.

THE MEDALS OF THE INTERNATIONAL MEDICAL CONGRESS.

To the Editor of THE LANCET.

SIR,—In the confusion of the Congress a box of Congress medals was lost. It may be that on this account some members of Congress or ladies may have failed to obtain them. If such persons will write to me the medals will be sent to them.

I am, Sir, yours faithfully,
W. P. HERRINGHAM,
Honorary General Secretary.
40, Wimpole street, W., Oct. 4th, 1913.

MEDICAL MAYOR. — Mr. R. Jones Evans, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed mayor-elect for Pwllheli.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—In connexion with the Faculty of Medical Sciences at University College, London, the following awards have been made :—Bucknill Scholarship (135 guineas) and First Medical Exhibition (55 guineas), divided equally between M. H. Oldershaw, of the Brighton Municipal Technical College and University College, London, and D. J. Thomas, of St. David's College School, Lampeter, and University College of Wales, Aberystwyth. W. Feldman, of the Central Foundation School and University College, London, is classed as second medical exhibitioner (without emoluments). Epsom Free Medical Scholarship: E. V. Corry.—The Goldsmid entrance exhibitions have been awarded as follows :—First exhibition: T. H. Somervell, Caius College, Cambridge. Second exhibition: J. Vincent Bates, Pembroke College, Cambridge. Proxime accessit: G. Y. Oliver, University College, London.

[2] THE LANCET, Jan. 2nd, 1909.

THE NATIONAL INSURANCE ACT.

SANATORIUM BENEFITS IN BIRMINGHAM.

A REPORT on the administration of sanatorium benefits for the year ending July 14th last has been issued by the Birmingham Insurance Committee. In consequence of the policy adopted by the city council it was possible to make early arrangements for the treatment of insured patients at the sanatoriums provided by the council. The first patient was admitted on August 24th, 1912, and a provisional scheme remained in force until July 14th of this year. The Local Insurance Committee has now entered into an agreement with the Birmingham corporation for a period of 30 years under which the corporation will provide the whole of the institutional treatment of insured persons suffering from tuberculosis, recommended by the committee, within the limits of the accommodation and facilities provided by the corporation's scheme for insured and non-insured persons, which when in full operation will include the following accommodation—viz., residential institutions (available for insured and non-insured persons): Yardley-road Sanatorium (including 50 beds reserved for children), 199 beds; Salterley Grange Sanatorium, 68 beds; West Heath Sanatorium, 52 beds; Romsley Hill Sanatorium, 100 beds provided by the Hospital Saturday committee, the corporation having arranged for the use of 90 beds. Dispensary accommodation is provided at the Broad-street Tuberculosis Dispensary for 2000 patients per week.

The treatment provided in the sanatoriums has been very widely appreciated, and the conduct of patients has been generally satisfactory. It has been necessary to expel a few owing to non-observance of rules, but all cases of expulsion have been investigated by the Committee and arrangements made for the patients to continue treatment in some other form, either dispensary or domiciliary. Fifty-eight patients neglected or declined to take advantage of sanatorium treatment, and 31 refused the dispensary treatment recommended. In some cases the reason given was the necessity to continue work in order to obtain means of subsistence for the family. In other cases treatment was declined because patients felt much better in health than when the application was made, and state that they will apply again if their condition changes. 1783 applications for sanatorium benefit were received, of which 1102 were from males and 681 from females. Of these 63 males and 58 females were ineligible on grounds other than health. Of the 1039 males referred by the Committee to the medical adviser for examination, 908 were members of Approved Societies, as were also 527 of the 623 females. During the year 834 males and 533 females were examined, 68 males and 20 females failed to attend for examination, and 137 males and 70 females were awaiting examination at the close of the year. Sanatorium treatment was recommended to 551 males and 347 females—337 males and 206 females to a course of six weeks; while 182 males and 152 females were ordered dispensary treatment. Domiciliary visits were suggested for 89 males and 31 females.

A table shows the occupational incidence of pulmonary tuberculosis, from which it appears the engineers sent the greatest number for treatment—this being 130 males and 18 females; while 104 general labourers were included. There are 103 domestic servants (including charwomen), 66 female press-workers, 43 warehouse workers and 36 clerks on the female side. The residential incidence varies from 3·9 per 1000 in St. Bartholomew's ward to 0·2 in North Erdington. The average for the whole city is 1·9 per 1000. The income for the year was £12,697 9*s.* 7*d.* and the expenditure £11,849 12*s.* 6*d.*, divided as follows: maintenance at sanatoriums, £6267 17*s.*; dispensary, £1142 15*s.* 6*d.*; domiciliary (estimated), £3622 10*s.* 3*d.*; medical examinations, £393; administration expenses, £350; incidentals, £73 9*s.* 9*d.*

THE MEDICAL PROFESSION IN GLOUCESTER AND MEDICAL AID ASSOCIATIONS.

At the recent quarterly meeting of the governors of the Gloucester Royal Infirmary and Eye Institution the following resolution passed by the honorary medical and surgical staff and forwarded to the general committee was read:—

> That the medical staff having been appealed to by the medical men practising in the Forest of Dean and other parts of Gloucestershire to support them in their endeavour to secure adequate remuneration for contract practices,' have decided that in the case of any medical a[illegible] employment of medical men [illegible] the medical profession they will [illegible] in consultation or have pro[illegible] holding office under any such [illegible] private patient or at the Royal Infirmary, and they must therefore decline to treat members of such associations except in those cases urgently requiring hospital treatment.

Two other resolutions explanatory of the situation were also read. The first, which had been passed by the Gloucestershire branch of the British Medical Association, was to the effect that [illegible] established in certain ar[illegible] Insurance Act, and havi[illegible] Benefit Subcommittee, such action was to be deemed inimical to the interests of the medical profession and constituted a breach of faith on the part of the insurance authorities. The branch therefore called upon the staffs of the Gloucestershire hospitals to refuse to recognise professionally those holding appointments in such associations, or to treat members of them except in circumstances of great emergency. The second resolution passed at a meeting of medical men practising in the city of Gloucester was as follows:—

> That this meeting of medical men in practice in the city of Gloucester considers the manner in which medical aid associations carry on their work as injurious to the interests of their patients and unfair to the doctors, and decides to refuse to recognise the staffs connected with these institutions. This meeting calls upon the staffs of all the hospitals in Gloucestershire to refuse treatment to medical aid patients except in cases of great gravity.

It is stated that the two last-mentioned resolutions have been signed by every member of the medical profession practising in the city of Gloucester.

HOSPITALS AND INSURED PATIENTS.

It is a matter of importance to hospitals, and particularly to those to the funds of which working men have been regular subscribers, that the circumstances in which, and the extent to which, insured patients are refused treatment at a particular institution should be made as clear as possible. The statement that insured persons will not be treated at a hospital is one easily made or repeated by a careless hearer without the necessary reservations, and so the story may gain ground that in no circumstances will any hospital treatment be given to a person who is insured. The usual proceeding is that all cases requiring immediate attention, as, for example, accidents, or such special treatment as only a hospital can give, will be treated, but that the hospital staff will not do for nothing that which medical men on the panel are receiving money to do. Attention has been called to this point recently at Cheltenham, and to the loss of income to which a hospital may be subjected by a misunderstanding which is excusable, but which can be removed by the proper explanation being given.

THE ALLOCATION OF INSURED PERSONS NOT MAKING THEIR CHOICE.

The question of the disposal of funds in the hands of Insurance Committees through insured persons not having chosen a medical man on the panel to attend them, and not having been distributed as the Act provides, and generall the question as to how their distribution is to be arranged for, have been occupying the attention of many committees besides that of London, including those of Cheshire, Surrey, Derbyshire, and the East Riding of Yorkshire. In the last-named district the patients who have not chosen their medical men appear to have been already distributed, but we understand that this has been done recently, and do not draw the conclusion that the difficulty which has arisen in London has been entirely avoided in the East Riding. [illegible] which has been emphasised by the [illegible] from Mr. Danckwerts, K.C., h[illegible] incial Insurance Committees referred to, but they will now have had their attention drawn to it. The method proposed to be adopted by any committee for the assignment of insured persons to practitioners on the panel, where no choice has been made by those persons, is one of those matters which has to be submitted to the Insuran[illegible] plan followed in the [illegible] Committee was consult[illegible] a given medical man as far as possible in numbers bearing the same proportion to the total number of persons to be so assigned, that the number on his list bears to the total of the insured persons who have made their choice.

MATERNITY BENEFIT AND A PROSECUTION.

The first prosecution under Section 19 of the National Insurance Act for neglect on the part of the husband to make adequate provision for his wife during and immediately after her confinement, after receiving maternity benefit, has taken place at St. Helens at the instance of the Cheshire Miners' Permanent Relief Society. The defendant received the money, gave his wife 2s. only, and was found lying drunk on her bed; the midwife had to buy milk for the patient and the relieving officer was called in. The defendant received a sentence of 14 days' hard labour, attention being called by the case to the provision in the section of imprisonment up to a month with or without hard labour, but without the option of a fine.

THE NUMBER OF INSURED PATIENTS TO BE ACCEPTED.

The Birkenhead Insurance Committee discussed recently the question of the number of insured patients that a medical practitioner should have on his lists. The general feeling, in the expression of which medical members of the committee took a prominent part, was that there was considerable danger of work being inadequately performed where private practice was undertaken in addition to 1500 or 2000 panel patients, the amount of private practice being an important factor. A motion was carried that the matter should be referred to the Medical Benefit Subcommittee to report upon, the chairman of the committee saying in introducing it that it would be well to know the views of the Local Medical Committee on the subject, and suggesting 2000 as a number which ought not as a rule to be exceeded. The question whether to impose a restriction might involve interference with the right of the insured to choose their doctors, he answered by saying that it was the duty of the committee to see that the insured had adequate attention, and that he had heard complaints made that insufficient attention was sometimes given.

CHANGE OF DOCTOR.

The period is approaching when patients who put themselves on the lists of those medical men who joined the panels early will find themselves able to exercise their right to select another medical attendant should they so desire, and owing to accessions to the panels will also find their range of selection enlarged. Notice has to be given in the case of desired change a month before the expiration of the existing period. It is, we fear, inevitable that it should be felt a hardship by medical men who have come late upon the panels when their former patients having the opportunity do not return to them. Equally the medical man who accepted promptly the situation created by the Act is likely to feel aggrieved when patients leave him for latecomers on the panel. It is to be hoped, however, that resentment or friction, if any arises, will be shortlived. The choice, in any case, will be that of the patient, and it has been the contention of the medical profession throughout that he should be free to exercise it.

THE BRISTOL BOARD OF GUARDIANS AND THE NATIONAL INSURANCE ACT.

At the last meeting of the Bristol board of guardians a resolution was moved to the effect that in future it should be obligatory on all officers appointed to the workhouses that they should be "on the panel" of the resident medical officer. A considerable discussion took place upon the matter, and it was stated that the motion was contrary to the provisions of the Act, which provided that insured persons should have the right under all conditions to select their own medical attendant. Eventually the proposal was defeated, on a division, by 7 votes.

ROYAL MICROSCOPICAL SOCIETY.—The next meeting of this society will take the form of a conversazione at King's College, Strand, on Wednesday, Oct. 15th, from 8 to 11 P.M.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology held on Sept. 25th, 26th, 29th, and 30th, for which 81 candidates presented themselves, of whom 51 were approved and 30 were rejected, the following candidates were successful:—

William Fletcher Barrett, Charing Cross Hospital; John Behesnilian, and Richard Vincent Bevan, Charing Cross Hospital and King's College; Antoun Bishara, St. Thomas's Hospital; Alberto Henriques Ferreira Bizarro, M.D. Lisbon, Lisbon University and University College; Edgar Scott Bowes, Guy's Hospital; Ingram Richard Rhodes Brogden, B.A. Cantab., Cambridge University and Guy's Hospital; Hari Chan, L.M.S. Punjab, Lahore Unversity; Raghunath Ganesh Dani, University College; Frank Philip Gilbert de Smidt, London Hospital; David McMurray Dickson, St. Thomas's Hospital; Geoffrey Barrow Dowling, Guy's Hospital; Nashed Fahmy, Cairo and King's College; Roy Fazan, Middlesex Hospital; Sourendra Mahon Ghosh, L.M.S. Calcutta, Calcutta University; Edward Austin Gibb, B.A. Cantab., St. Thomas's Hospital; Farid Yusif Hassaballa, University College; Wilhelm Otto Holst, Middlesex Hospital; John Robert John, University College, Cardiff; Llewellyn Price Johns, King's College; Dadabhai Nowroji [illegible] University and University [illegible] College; Dhanjishaw Phir[illegible] Bombay University and L[illegible] Mesurier, London Hospital [illegible] Hospital; Francis Keene [illegible] Raghunath Mirajkar, L.M. & S. Bombay, Bombay University and St. Bartholomew's Hospital; Ernest Cecil de Mallet Morgan, Guy's Hospital; Frederick Maurice Mosely, B.A. Cantab., Cambridge University and London Hospital; Bidhan Prosad Mozoomdar, L.M. & S. Calcutta, Calcutta University; Sinnethamby Muttiah, London Hospital; Canapathy Pillai Nagamuttu, Ceylon Medical College and Middlesex Hospital; Wilfrid Guy Stuart Neely, L.D.S. Eng., Guy's Hospital; Baddeliyanage Don Hugo Philip, Ceylon Medical College and London Hospital; Robert Louis Portway, Guy's Hospital; Charles Young Roberts, St. Thomas's Hospital; Abdel Raoof Roushdy, Cairo and King's College; Percy Gunn Russell, Middlesex Hospital; Bishambhar Sahai, Calcutta University; James Ernest Scanlan, St. Mary's Hospital; Ronald James Scarr, Manchester University; John Milnes Smith, Middlesex Hospital; Godfrey Trehane Symons, King's College; John Aylmer Tippet, St. Thomas's Hospital; Martin Baird Moore Tweed, *Guy's* Hospital; Douglas James Valentine, London Hospital; Harry Cecil Craven Veitch, University College; Herbert Stewart Wacher and Leonard Pengelly Waghorn, Guy's Hospital; and Alban Wilson and Ismail Zaki, University College.

FOREIGN UNIVERSITY INTELLIGENCE.—*Stuttgart:* Dr. Karl Baisch, professor of obstetrics in the University of Munich, has been appointed Chief Physician to the new Gynæcological Department of the Municipal Hospital of St. Katherine.—*Vienna:* Dr. Jakob Erdheim has been recognised as *privat-docent* of Pathological Anatomy.

MANCHESTER ROYAL INFIRMARY OLD RESIDENTS' CLUB.—A meeting of this club will be held at the Midland Hotel, Manchester, on Saturday, Oct. 18th, at 6.30 P.M. The meeting will be followed, at 7 P.M., by a dinner, at which Mr. George H. Pinder will preside. Any old resident who has failed to receive a notice is requested to apply to the secretaries, Royal Infirmary, Manchester.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—The following is the result of the Entrance Scholarships examinations at this school:—University Scholarship, J. J. O. Beven (Cambridge); First Entrance Scholarship, S. C. Shaw; Second Entrance Scholarship, O. L. C. Sibley; Third Entrance Scholarship, G. F. W. Howorth; and Freer Lucas (Epsom) Scholarship, L. W. Hefferman.

DONATIONS AND BEQUESTS.—By will the late Mr. William Weir, of Kildonan, has left £10,000 each to the Glasgow Royal Infirmary and the Glasgow Western Infirmary, £5000 each to Glasgow Victoria Infirmary and the University of Glasgow for additional assistant to the professor of materia medica, £2000 each to the Kilmarnock Infirmary and the Ayr Infirmary, and £500 each to the Glasgow Eye Infirmary and the Glasgow Ophthalmic Institution.—By the death of Mr. Thomas Ryder, of Harrogate, a sum of £20,000, left by his wife to build and endow a hospital at Middleton, subject to the life interest in this sum of her husband and her mother, has now become available for building and endowing a hospital at Middleton, Lancs.—Dr. John Albert Nunneley has left a sum of nearly £45,000 before deduction of legacy duty to the Leeds General

Infirmary and the Royal Mineral Water Hospital, Bath. The first-named institution will receive two-thirds and the other one-third.

THE temporary address of the Wellcome Bureau of Scientific Research until further notice will be 54A, Wigmore-street, London, W.

THE University Scholarship at St. Thomas's Hospital has been awarded to H. H Monk Gould, of Charterhouse and Clare College, Cambridge.

THE Order of the Red Eagle, Third Class, has been conferred upon Surgeon-General W. Schultzen, of the War Office, Berlin.

Dr. Bruegel, of Munich, has been granted the rank and title of Court Physician.

HARVEIAN SOCIETY OF LONDON.—This society will hold a clinical meeting at 8 P M. on Thursday, Oct. 16th, at Paddington Green Children's Hospital, when Dr. Leonard G. Guthrie will take the chair. Cases will be shown by the hospital staff. Members wishing to show cases are requested to communicate with the honorary secretary, Mr. Duncan C. L. Fitzwilliams, 31, Grosvenor-street, Grosvenor-square, W.

CENTRAL LONDON THROAT AND EAR HOSPITAL.—The winter session of the Central London Throat and Ear Hospital, Gray's Inn-road, will commence on Friday, Oct 17th, when Dr. Thomas James Walker will deliver the inaugural address, "*Laryngoscopy 1860 to 1913: a Retrospect*," at 3 P.M The annual dinner of the staff with past and present students will take place the same evening at the Trocadero Restaurant, Dr. Dan McKenzie being in the chair.

LITERARY INTELLIGENCE.—We understand that a French translation by Professor Léon Guinet of the second edition of Dr. H. Charlton Bastian's work "The Origin of Life" has been published by H. Lamertin, of Brussels The article by Dr Bastian entitled "Spontaneous Generation: its Reality and what it Implies," which appeared in the June number of the *English Review*, has also been translated into French, and is published in the *Revue Scientifique* for Sept. 27th.

THORP.—On Oct. 3rd, at Henley-road, Ipswich, from pneumonia, Henry John Thorp, M.D., aged 81 years.

WALKER.—On Sept. 30th, as the result of an accident, Henry George Walker, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HEALTH AND HOSPITALS IN GAMBIA.

A REPORT by Mr. W. T. Campbell, Colonial Secretary of Gambia, on the Blue book of the colony for 1912 has been issued as a Parliamentary paper. It gives the population of the colony as 7700 and of the protectorate as 149,463. The number of Europeans, including females, residing in the colony and protectorate during the year was 193. Of these, 17 were invalided and 3 died. The general health was satisfactory and the year was fortunately free from yellow fever, of which there had been an outbreak in 1911. There were 1914 vaccinations performed in Bathurst and 867 in the protectorate. Arrangements have been made for a medical officer to travel through the protectorate and carry out vaccinations, and it is hoped that this will give more satisfactory results. The campaign against mosquitoes has been vigorously carried out, and has resulted in greatly diminishing their number. After the last case of yellow fever in November, 1911, the fumigation of all Government quarters, cellars, and many private buildings was undertaken. The stegomyia species of mosquito has almost disappeared. Among the mosquitoes found in different parts of Bathurst at the end of the year only two were stegomyia; the remainder were mainly culex. The clearing of about 40 acres of mangrove on the western side of the town has greatly diminished the number of mosquitoes in that quarter. The climate of the Gambia is pleasant during the dry season, which lasts from November to May. For the remaining months the conditions are similar to those experienced elsewhere on the West Coast of Africa. The damp and enervating weather is very oppressive and more generally felt, after the several rainless months, than is the case elsewhere. The highest shade temperature recorded in Bathurst in 1912 was 104° F. and the lowest 58°. The rainfall was 33.99 inches.

The hospital at Bathurst has accommodation for 4 first class, 11 second-class, and 10 third class male patients and 15 female patients, including two cots for children. There are also four rooms for isolation cases. The wards for males and females are in separate buildings. A new hospital at MacCarthy Island was opened in 1911, *and is in charge of a European medical officer. It contains a ward for* Europeans and three wards for native patients. There is also a contagious diseases hospital, situated about two miles from Bathurst. Four mild cases of small-pox, all of which recovered, were treated in *this building during the year. The total number of patients treated* in the Bathurst Hospital was 529, of whom 33 died, and in the out-patients' department 7893. At the MacCarthy Island Hospital 66 in-patients and 1356 out-patients were treated.

A DELETION FROM THE MEDICAL DIRECTORY.

To the Editor of THE LANCET.

SIR,—I asked the authors of this useful book if they intended to indicate a practitioner was "on the panel," and they inform me they do not mean to show the distinction. The Directory will be worthless to me, and I have told them to delete my name. I do not intend that the public shall wonder whether I am a "panel doctor." This matter is of immense importance to the profession and the public generally.

I am, Sir, yours faithfully,
JAMES BRASSEY BRIERLEY, M.D. Edin.

Manchester, Oct. 6th, 1913.

TUBERCULOSIS AND THE CINEMATOGRAPH.

To the Editor of THE LANCET.

SIR,—Can any of your readers tell me where cinematograph films suitable to illustrate a popular lecture on consumption can be obtained?

I am, Sir, yours faithfully,
Earl Shilton, Hinckley, Oct. 6th, 1913. PHILIP GELL GARRETT.

"WORM NODULES" IN AUSTRALIAN BEEF.

THE Australian Institute of Tropical Medicine, established in 1903 and enlarged in 1912, has already done good work. The annual report for 1911, now before us, is written by the director, Dr. Anton Breinl, in collaboration with his two colleagues, Mr. Frank H. Taylor, F.E.S., and Dr. T. Harvey Johnston, D.Sc. The institute, situated at Townsville in North Queensland, now receives an annual subsidy of £4000 from the Federal Government of Australia, and judging from the report now before us has already more than justified its existence. One of the chief investigations carried out was that directed towards *the solution* of the problems connected with the occurrence of "worm nodules" (onchocerciasis) caused by Onchocerca gibsoni in Australian beef, an important subject to which we directed the attention of our readers in THE LANCET of Feb. 4th, 1911. *Although the researches under*taken by the experts of the Australian Institute have not succeeded as yet in demonstrating the complete life-history of the parasite, it may nevertheless be said that these investigations have cleared up a number of doubtful points; they have, for instance, definitely excluded mosquitoes, stomoxys calcitrans, and leeches as being intermediary hosts. Unfortunately, the wet season of 1911 was light and therefore unfavourable to the inquiry, experience having shown that the best opportunities for such a research are furnished by a heavy wet season in which a rich insect fauna is present.

THE INDIAN CIVIL SURGEON OF THE PAST.

A DESCRIPTION in the *Indian Planter's Gazette* of the civil surgeon of the dim past shows the progress made in India in the matter of medical attendance :—

> You would hardly guess from his appearance and ways that he was a surgeon and a medical man. He certainly does not smell of lavender or peppermint, or display fine or curious linen, or tread softly like a cat. Contrariwise he smells of tobacco, and wears flannel underclothing. His step is heavy. He is a gross, big, cow-buffalo sort of man, with a tangled growth of beard. His ranting voice and loud familiar manner amount to an outrage. He laughs like a camel, with deep bubbling noises. Thick corduroy breeches and gaiters swaddle his shapeless legs, and he rides a coarse-bred Waler mare. I pray the gods that he may never be required to operate upon my eyes, or intestines, or any other delicate organ.

THE IDEAL BREAKFAST.

To the Editor of THE LANCET.

SIR,—*A propos* of your recent annotation on "meals" may I suggest that—

"*Un œuf* is as good as a feast"

sums up the true philosophy of breakfast diets.

I am, Sir, yours faithfully,

Oct. 8th, 1913. W. B. A.

MEDICAL AFFAIRS IN FIJI.

THE report on the Blue-book of this colony for the year 1912 estimates the total population at 149,179, made up of 4131 Europeans, 2512 half-castes, 48,614 Indians, 2769 Polynesians, 1965 Rotumans, 87,833 Fijians, 397 Chinese, and 958 others. The total rainfall recorded at Suva during the year was 115·406 inches. The highest temperature in the shade was 92·0° F. on March 18th, and the lowest 60·0° on August 25th. The Colonial Hospital at Suva, the principal medical institution, is under the charge of a resident medical officer, assisted by a junior medical officer, a matron, two staff nurses, one graduate nurse, and six pupil nurses, the whole being supervised by the chief medical officer. Admissions during 1912 numbered 1728, of whom 211 were Europeans. There is a branch hospital at Levuka under the charge of the district medical officer, assisted by a matron. This institution provides for the treatment of Europeans as well as natives. There are eight provincial hospitals for the treatment of native Fijians. These are supervised by Government medical officers. The number of admissions to these provincial hospitals during 1912 was 3917. There is a leper asylum on the island of Makogai, under the charge of a medical superintendent, assisted by two European nursing sisters and two native medical practitioners. On Dec. 31st, 1912, there were 154 lepers in the asylum. The work of collection and transportation of lepers formerly residing in all parts of the colony is now nearing completion.

M.D. (Accrington).—Yes.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SPECIAL MEETING OF FELLOWS: at 5.30 P.M.

Demonstration by Dr. Hideyo Noguchi of the Rockefeller Institute.

(1) Pure Cultures of Various Spirochætæ (Treponema pallidum, T. pertenue, T. microdentium, T. macrodentium, T. mucosum, T. calligyrum, T. refringens).
(2) Transmission of Syphilis to Animals by means of Pure Cultures of Treponema pallidum.
(3) Demonstration of Treponema pallidum in the Brain of General Paralytics.
(4) Transmission of Treponema pallidum from the Brain of General Paralytics to the Rabbit.
(5) Production of Symptoms and Lesions resembling General Paralysis in the Rabbit by means of an Intracerebral or Subdural Inoculation with Treponema pallidum.
(6) Cultural Studies of the Virus of Rabies.

Illustrated by Lantern Slides.

TUESDAY.

SECTION OF SURGERY (Hon. Secretaries—J. Murray, Raymond Johnson): at 5.30 P.M.

Mr. Charles A. Pannett: The Selection of the Incision in Cœliotomy.

Mr. Frank Kidd: Pyeloradiography.

Short Historical Survey and Description of the Method. Applications in Practice. Examples will be shown to Illustrate the Diagnosis of Congenital Abnormalities of the Kidney and Ureter, Dilatation of the Kidney, Stone in the Kidney, Abdominal and Renal Neoplasms, &c. Skiagrams exhibited by Mr. Gilbert Scott. Experimental Studies to show the Effect on the Kidney of the Injection of Colloid Silver into the Renal Pelvis. Pathological Reports by Dr. H. M. Turnbull, Experimental Work by Mr. E. C. Lindsay.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—J. M. H. MacLeod, S. E. Dore): at 5 P.M.

Dr. Haldin Davis: Demonstration of Coloured Lantern Slides of Skin Diseases made by the Paget Prize Process.
Dr. Knowsley Sibley: Case of Nævus Linearis Bilateralis.
Dr. J. M. H. MacLeod: Case for Diagnosis.

And other Cases.

FRIDAY.

SECTION OF OTOLOGY (Hon. Secretaries—G. J. Jenkins, G. N. Biggs): at 5 P.M.

Mr. W. M. Mollison: Case of Fracture of the Skull with Injury to the Cranial Nerves.
Mr. Sydney Scott: Cas [illegible] with Rapid Recovery afte [illegible]

And [illegible]

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—Cecil R. C. Lyster, S. Gilbert Scott): at 8.30 P.M.

Clinical Evening:
Members are invited to bring Specimens, Cases, or Plates.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., General Meeting. 8 30 P.M., The President (Sir David Ferrier, M.D.):—Introductory Address Paper:—Dr. F. Buzzard: Varieties of Facial Spasm and their Treatment.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY.—5 P.M., Prof. Keith: Specimens illustrating the Lesions of Achondroplasia, Osteogenesis Imperfecta, and Allied Conditions. (Museum Demonstration.)

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced:—

April 28th-Nov. 6th (Ghent).—International Exhibition.
May 31st to October (London, Earl's Court).—Imperial Services Exhibition.
May-October
June 24th-Oc
M
Wellcome.)
June-October (London, Crystal Palace).—Anglo-German Exhibition.
Oct. 1st-Nov. 1st (London, Shepherd's Bush).—National Gas Exhibition
,, 9th-25th (London, Olympia).—Ideal Home Exhibition.
,, 22nd-25th (Berlin).—Eleventh International Anti-Tuberculosis Conference.
,, 28th-Nov. 1st (*London, Royal Horticultural Hall*).—Twenty-fourth Universal Cookery and Food Exhibition.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial Staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.	£	s.	d.
One Year	£1	1	0
Six Months	0	12	6
Three Months	0	6	6

TO THE COLONIES AND ABROAD.	£	s.	d.
One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

A.—Ardath Tobacco Co., Lond.; Dr. J. P. Aiken, Camlough; Dr. D. E. Anderson, Paris; Avondale, Southbourne-on Sea; Mr. J. W. Arrowsmith, Bristol; Anglo-American Pharmaceutical Co., Croydon; Dr. R. W. Allen, Lond.; Dr. M. El Aroosy, Cairo; Dr. D. E. Anderson, Highgate; Messrs. Claudius Ash, Sons, and Co., Lond.

B.—Messrs. C. Birchall, Liverpool; Mr. C. S. Buck, St. Albans; Mr. W. T. Beswick, Cambridge; Messrs. Bruce, Green, and Co., Lond.; Dr. Andrew Balfour, Lond.; Mr. W. Bentley, Lancaster; Messrs. A. J. Burckhardt and Co., Lond.; Surgeon J. L. Barford, R.N., Simonstown; Birmingham Corporation, Treasurer to the; Dr. J. Mitchell Bruce, Lond.; Mrs. Cloudesley Brereton, Lond.; Mr. R. C. Brown, St. Kilda; Dr. J. B. Brierley, Manchester; Dr. A. Besredka, Paris; Bath Royal United Hospital, Secretary of; Mr. Albert Benthall, Lond.; Bury Infirmary, Secretary of.

C.—Messrs. J. and A. Churchill, Lond.; Dr. Cunliffe, Manchester; Mr. W. A. Crosbee, Malvern; Clayton Hospital, Wakefield, Hon. Secretary of; Messrs. Curling, Wyman, and Co., Lond.; Messrs. Clarke, Son, and Platt, Lond.; Dr. J. Cates, St. Helens; Messrs. Corbyn, Stacey, and Co., [illegible] Lond.; [illegible] ng, [illegible] ns, Lond., Clerk to the; Mr. F. W. Clarke, Chorlton-cum-Hardy; Messrs. Carnrick and Co., Lond.; Mr. H. A. Collins, Croydon.

D.—Messrs. W. Dawson and Sons, Lond.; *Daily Mail*, Lond., Directors of; Dr. Patrick W. Diack, Lond.; Dr. Downer, Matlock; D. J. M.

E.—Dr. A. M. Elliot, Lond.; Messrs. Elliott, Son, and Boyton, Lond.

F.—Ford M [illegible] Forward [illegible] ham; Mr [illegible] Mr. Geor[illegible] and Foster, Lond.; [illegible] Lond.; Dr. Paul Fildes, Lond.; Messrs. Ferris and Co., Bristol; Dr. Fielden, Wengen.

G.—Gartloch Hospital, Gartcosh, [illegible] of; [illegible] Hon. [illegible] of Bengal in Council, Calcutta; Dr. Eric Pearce Gould, Lond.; Dr. A. C. Gemmell, Brighton; General Electric Co., Lond.; Dr. Philip Gell Garrett, Earl Shilton; Guild of St. Luke, Sutton, Hon. Secretary of; Gloucestershire Royal Infirmary, Gloucester, Secretary of; Mr. J. Green, Lond.

H.—Mr. C. J. Hersey, Lond.; Dr. B. Hudson, Davos-Platz; Messrs. G. Head and Co., Lond.; Sir J. P. Hewett, Lond.; H., Acton; Mr. F. A. Hocking, Lond.; Dr. R. J. Hillier, Sheffield; Dr. W. P. Herringham, Lond.; Dr. J. Hay, Liverpool; Major L. W. Harrison, R.A.M.C., Lond.; Dr. C. F. Harford, Leyton; Mr. N. Bishop Harman, Lond.; Dr. D. Berry Hart, Edinburgh; Messrs. Harrison and Sons, Lond.; Holloway Sanatorium, Virginia Water, Medical Superintendent of; H. L.

J.—Miss E. M. Johnstone, Virginia Water; Messrs. J. F. Jones and Co., Paris.

K.—Messrs. H. S. King and Co., Lond.; King Edward Memorial Hospital, Lond., Secretary of; Messrs. Kutnow and Co., Lond.; Prof. A. Keith, Lond.

L.—London Temperance Male and Female Nurses' Co-operation, Lond., Secretary of; Messrs. Lepper, Lond.; London Press Exchange, Manager of; Messrs. Longmans, Green, and Co., Lond.; Mr. H. K. Lewis, Lond.; Leeds General Infirmary, Secretary of; Mr. A. Le Forestier, Lond.; [illegible] rd, Lond., [illegible]; Leeds [illegible] retary of; Dr. R. A. Lyster, Winchester; Leicester Royal Infirmary, Secretary of.

M.—Mr. R. Mosse, Berlin; Mr. R. Mosse, Cologne; Miss E. C. Macirone, Newcastle-on-Tyne; Mr. Cortlandt Macmahon, Lond.; Miss E. F. MacKinnon, Nairn; Mr. R. Matthews, Sheerness; Dr. P. W. MacDonald, Dorchester; Maltine Manufacturing Co., Lond.; Dr. Alexander Morison, Lond.; Dr. A. Macdonald, Lond.; Messrs. C. and E. Morton, Lond.; Dr. A. W. Meyer, Quincey; Mr. E. W. Marshall, Manchester; Messrs. Mather and Crowther, Lond.; Mr. E. Merck, Lond.; Mr. J. Murray, Lond.; Medical Agency, Lond., Secretary of; Messrs. J. Murdoch and Co., Lond.; Manchester Corporation, Clerk to the; Dr. M.; Macclesfield General Infirmary, Secretary of.

N.—Mr. H. Needes, Lond.; Northampton County Asylum, Secretary of; Newcastle-upon-Tyne Education Committee, Secretary of; National Dental Hospital, and College, Lond., Dean of; *Nursing Times*, Lond., Editor of; *North Ormesby Hospital*, Middlesbrough, Secretary of; Newcastle-upon-Tyne Hospital for Sick Children, Secretary of.

O.—Mr. Edmund Owen, Lond.; Sir William Osler, Bart., Oxford; Mr. W. D. O'Kelly, Dublin; Oldham Royal Infirmary, Secretary of; Oxford Eye Hospital, Secretary of.

P.—Mr. P. Paterson, Glasgow; Mr. R. H. Paramore, Bembridge; Mr. J. E. Purvis, Cambridge; Messrs. C. Pool and Co., Lond.; [illegible] Smith, Croydon; [illegible] Lond.

R.—Mr. D. Ram, Almora; Royal Eye Hospital, Lond., Secretary of; Dr. J. A. Rivière, Paris; [illegible] ary of; [illegible] thsea; [illegible], Newcastle-on-Tyne, Secretary of; Royal South Hants and Southampton Hospital, Secretary of; Rousay Parish Council, Clerk to the; Royal Naval Medical Service, Lond., Director-General of; Royal College of Surgeons of England, Lond., Secretary of; Royal Portsmouth Hospital, Secretary of; Royal Halifax Infirmary, Secretary of; Messrs. Rhys Roberts and Co., Lond.

S.—Messrs. Swain, Hunnybun, and Taylor, Lond.; Messrs. Spottiswoode, Dixon, and Hunting, Lond.; Mr. J. Saul, Southport; Dr. Fred J. Smith, Lond.; Colonel Bruce Skinner, R.A.M.C., Lond.; Dr. Agnes Savill, Lond.; Dr. J. Edward Squire, Lond.; Dr. Josef Schnierer, Vienna; Sheffield Union, Clerk to the; St. Marylebone General Dispensary, Lond., Secretary of; Dr. J. Sinclair, Lond.; Messrs. W. B. Saunders Co., Lond.

T.—Dr. W. Bramley Taylor, Lond; Mr. J. W. Thomson, Wakefield; Dr. John Tatham, Old Oxtead; Dr. William J. Tulloch, Newcastle-on-Tyne.

U.—University of Glasgow, Registrar of.

W.—West Herts Hospital, Hemel Hempstead, Secretary of; Mr. Wallace, Lond.; Waterbury Chemical Co., Des Moines; West Riding County Council, Wakefield, Clerk to the; Dr. G. F. Whyte Dundee; Mr. C. A. Wallace, Aberdeen; Dr. C. Wal[illegible] mersdale.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. J. M. Atkinson, Lond.; Aberystw[illegible] Secretary of; [illegible] Messrs. [illegible] Lond.; A. A. M.; A. P.

B.—Dr. R. P. Beatty, Swindon; Dr. G. S. Blandy, St. Albans; Mr. C. S. Bowker, Pontnewydd; Bolton Infirmary, Secretary of; Dr. Buckmaster, Lond.; Mr. E. Bougault, Paris; Messrs. Brackstone and Co., Colwyn Bay; Dr. S. A. Bonnerjee, Lond.; Messrs. T. B. Browne, Lond.; Bank of Bombay, Bombay, Manager of; Dr. J. C. Bowie, Cardiff; Dr. [illegible] Banner's Food [illegible] Mr. [illegible] mou[illegible] Nottingham.

C.—Dr. Curtis, Lond.; Messrs. Cutting and Underwood, Lond.; Messrs. T. Christy and Co., Lond.; Messrs. Crossley and Co., Lond.; Mr. G [illegible] Mr. J [illegible] Dr. F [illegible] Cook, [illegible] man, Wednesbury.

D.—Mr. M. E. Dovaston, Lond.; Dr. M. Dockrell, Lond.; Dr. J. W. Duffus, Port Elizabeth; Professor Delépine, Manchester; Dr. W. T. Dougal, Pittenweem; Dorland Agency, Lond.

E.—Mr. A. R. Elliott, New York; Dr. C. Enfield, Jefferson, U.S.A.

F.—Messrs. Flood and Sons, Lond.; Mr. W. V. Field, Kimberley; Fifth Avenue Bank, New York, Manager of.

G.—Dr. T. H. Gibson, Kirkby Stephen; Dr. S. Gill, Formby; Mr. H. S. Gettings, Wakefield; Mr. H. W. Goodman, Lond.; Mr. M. Greer, Corris.

H.—Mr. A. W. Hayward, Bournemouth; Messrs. C. J. Hewlett and Son, Lond.; Harrogate Hydropathic Co., Manager of; Mr. H. G. Hirons, Lewes; Haydock Lodge Retreat, Newton-le-Willows, Secretary of; Messrs. Hastings Bros., Lond.

J.—Mr. W. H. Jalland, York; Mr. W. Owen Jones, Bowdon; Mr. T. Jubb, Lytham.

K.—Mr. D. C. Kelly, Carnarvon; Mr. C. Kerr, Truro.

L.—Mr. C. B. Lockwood, Lond.; Messrs. Leach and Son, Wisbech; Leicester Mental Hospital, Secretary of; Mr. Long, Dover; Lyon, Lond.

M.—Dr. H. C. Martin, Caerleon; Messrs. J. Mundy, Gilbert, and Co., Birmingham; Mr. A. L. Moreton, Lond.; Mr. J. E. May, Lond.; Dr. M. Martin, Glasgow; Dr. T. W. Martin, Pengam; Dr. A. W. Mackay, Inverness; Dr. F. Meyer, Melbourne; Mundesley Sanatorium, Secretary of; Mr. G. B. Messenger, Sheffield; Mr. B. Miller, Lond.

N.—Mr. A. W. Nuthall, Birmingham; Northampton County Borough Education Committee, Secretary of; North Lonsdale Hospital, Barrow-in-Furness, Treasurer of; Nurse, Builth Wells.

P.—Miss C. Pring, Bristol; Messrs. G. Pulman and Sons, Lond; Mr. E. Pearson, Ulverston; Pearson's Antiseptic Co., Lond, Secretary of.

Q.—Queen's University of Belfast, Bursar of.

R.—Mr. H. M. Riley, Leicester; Messrs. Roden and Wilkinson, Droitwich; Mr. H. C. Ross, Lond.; Mr. J. Rampton, Ascot; The J. D. Riedel Co., Lond.; Reuter's Telegram Co., Lond.; Mr. W. Ramsay, Melbourne; Royal Buckinghamshire Hospital, Aylesbury, Secretary of; Messrs. Reitmeyer and Co., Lond.; Rev. B. Rust, Lond; Dr. S. Rideal, Lond.

S.—Mr. G. O. Stamper, Skegby; Messrs. G. Street and Co., Lond; Messrs. Spiers and Pond, Lond; [illegible] Manager [illegible], Aber- [illegible] Smith, [illegible] Corporation, Accountant to the; Dr. G. I. T. Stewart, Ipswich; Messrs. Snaith and Sons, Darlington.

T.—Dr. C. C. Twort, Lond.; Messrs. Trever and England, Hull; Mr. T. W. Thomas, Caerphilly.

V.—Dr. J. Valentine, Maybole; Mr. O. Vevers, Norton.

W.—Messrs. Winter, Birmingham; West Ham and Eastern General Hospital, Lond., Secretary of; Messrs. W. Wood and Co., New York; W. E. G.; Warrington Infirmary, Secretary of; Dr. C. Woodhouse, Esher; Rev. G. H. Williams, Remenham; Dr. A. Watson, Stone.

Y.—Dr. Meredith Young, Chester.

Z.—Messrs. A. and M. Zimmermann, Lond.

An Address

ON

HEREDITY AND INHERITANCE AS THEY CONCERN THE PHYSICIAN.

Delivered before the Birmingham Society for the Study of Heredity

BY CHARLES MERCIER, M.D. LOND.,
F.R.C.P. LOND.

MR. PRESIDENT AND GENTLEMEN,—I take it that in inviting a physician, whose profession embraces a very outlying region of biology, to address you on the central theme of this science, which is not his proper subject, and as to which he is an outsider, your object is to learn what bearing the great problems of heredity and inheritance have upon the practice of the physician; how far they influence his views of the nature of disease; how far they modify in his opinion the fate of his patients; and how far and in what way he takes them into account in the advice he gives. This, I say, is my surmise; but it may be that you merely had in your minds an address that I gave in this city a year ago, and based your invitation on the ground that however erroneous the doctrine might be, you would at least hear something racy. If this was your intention I am afraid you will be disappointed. I have nothing to tell you that is not quite humdrum and not much that you have not heard before.

As I have said, I am not an expert in that central realm of biology that includes the problems of heredity and inheritance; but at the same time, in my capacity as a physician engaged in the treatment of mental disease, I have constantly to take these problems into account, for it is impossible, I will not say to understand these diseases, for I do not profess to understand them, but it is *impossible in many cases* to form a trustworthy opinion or to give trustworthy advice without taking heredity and inheritance into account.

EUGENICS.

We hear a great deal nowadays about eugenics, and some of us hear so much about it that we get rather tired of aspirations, praiseworthy, no doubt, but for the most part extremely vague, for the coming of a millennium in which marriages will be arranged by a committee of experts—an expert, I may explain, is a person who is omniscient on one subject and knows very little about any other: I ought to [illegible] on [illegible] most [illegible] of qualities—they breed cows with an eye to milking capacity, steers *for rapid growth and early maturity, poultry for* feather and comb, or perhaps for laying fertility, hounds for speed and scent, and so forth; but the controllers of eugenics in the human race are to breed for a vast number of complex qualities, *and to breed for them all at once.* They are to breed for physical robustness and capacity to resist disease, f[illegible] immunity from sea-sickness; the representative of commerce will look to pushfulness and skill in bargaining; the representative of the *Church will breed for ability* to conduct clubs for working men and mothers' meetings; the representative of art will breed for ability, if not to paint pictures, at least to buy and pay for them; and all will combine to produce a breed of physicians who will practise without desiring fees. I [illegible] ubject [illegible] No [illegible] when [illegible] y the State. We see in everything, from the treatment of suffragettes to the administration of the telephones, how vastly superior is State regulation to the enterprise of private individuals.

A Hypothetical Case as to the Expediency of Marriage.

Eugenics has a peculiar interest for me, because I am often asked to advise on the expediency, from an eugenic point of view, of a marriage. I have no reason to believe that my advice is ever taken, but it is often asked for, and sometimes even paid for, and therefore I have no reason to complain. It *sometimes happens, and cases* of the kind may have come under the observation of some of those here present, that a young man, who may even be middle-aged, becomes enamoured of a young woman to such a degree that he becomes engaged to marry her. And it sometimes happens—and again some of you may be able to corroborate my statement—that after a certain length of engagement he realises the truth of that wise prediction expressed by a neighbouring nation in the well-known words:—

> Tu t'en repentira, Colin,
> Tu t'en repentira;
> Car si tu prends une femme, Colin,
> *Tu t'en repentira.*

In such a case several courses are open to the penitent. He may flee to foreign parts; he may stand the racket of an action for breach of promise; or he may, and often does, come to me and say: "Doctor, I have conscientious scruples. My family positively reeks of insanity. My father's second cousin's first husband drank a barrel of beer a day, and ended his life by spontaneous combustion. This being so, is it not certain that if I marry dear Jemima Brown I shall certainly go raving mad and cut her into little bits? At the present moment I feel so frightfully nervous that if you give me a certificate to this effect I feel confident that I shall so far forget myself as to double your fee." These may not be his precise words, perhaps, but this is the purport of the confidences that I sometimes receive when I am asked to give an opinion on an individual case of eugenics.

The Biometric and Mendelian Methods.

My rule is to decide all cases on general principles, and in accordance with this rule I consult the works of acknowledged authoriti[illegible] eminent statistician and [illegible] and I obtain from him [illegible]osing X to be the character in the parent, and Y the mean character in the offspring, then the equation is

$$Y = A + B \cdot X,$$

where A is a dimension of the same nature as X or Y, and B is a number that will vary from case to case. My difficulty is to know what particular variation of B applies to the case before me; and as Professor Karl Pearson tells me nothing about this, I am unable to apply the formula, and am obliged to turn to his rival and antagonist, Professor Bateson, to see what light the laws of Mendel will throw upon my difficulty.

From Professor Bateson I learn that when a dominant is crossed with a recessive the offspring will all exhibit the dominant character; but in the next generation the dominants will be to the recessives as 3 : 1, and of the three dominants only one will be a pure dominant, the others having the recessive character latent. It is perhaps my density which prevents me from learning from these premisses whether the fact of his father's second cousin's first husband's having drunk a barrel of beer a day will cause Mr. Jones to cut Jemima Brown into little bits in case they should be united in the bonds of holy matrimony. Perhaps it is my density, and I may be unduly biassed in my own favour when I decide that it is not, and that neither the laws of Mendel nor the equations of biometry are of the slightest value in the determination of individual cases. It is manifest on the face of them that they cannot be, and for this reason. The methods of Galton and Pearson are applicable to large numbers, and to large numbers only, *and do not yield results that are even approximately true* until the numbers become very large. To apply biometrics to individual *cases is much* like comforting a convicted and condemned murderer by saying, "Cheer up! There are *only 15 persons hanged every year* in this country out of a population of 40 millions; so that it is 2,666,666·6, &c., to 1 that you won't be hanged!"

The Mendelian method of Professor Bateson is equally *inappropriate.* It tells me that if the father of my patient was a drunken lunatic, and his mother was a paralysed dement, and if the father's drunkenness is dominant and lunacy recessive, while in the mother paralysis is dominant and dementia recessive, and if they have 16 children, then the chances are that nine children will be paralysed drunkards, three will be demented drunkards, three will be paralysed lunatics, and one will be a demented lunatic. This is very interesting, but it is not what I want to know.

I want to know what the chances are that poor Jemima Brown will be cut into little bits in the improbable event of her compelling Mr. Jones to marry her.

Inutility of Biometrics and Mendelism to the Practising Physician.

I have chosen an outside case to illustrate the thesis that I wish to establish, which is that neither biometrics nor Mendelism is of the slightest value to the practising physician. Mendelism has proved its utility in another field by enabling breeders to produce certain strains of wheat and other stock that could not have been produced, or could not have been so rapidly produced, without its aid; and biometrics has no doubt its value in another field by showing the general trend of variation in a large population; but neither of them can be applied to individual cases, and as it is with individual cases that the physician is concerned, neither of them has the slightest value for the physician, and as a physician he is no better off than if Galton and Pearson and Mendel and Bateson had been untimely births which never saw the light.

Seeing that I have already declared that a physician practising in mental disease cannot practise efficiently without taking into account both heredity and inheritance, and seeing that I have now declared that the two accepted—and may I say fashionable?—methods of investigating the facts of heredity and inheritance are quite useless to him, the question arises, What is his attitude to these problems? How does he take them into account? What are the aspects of them that he has to consider?

THE NATURE OF REPRODUCTION.

In order to answer these questions I must lay before you two hypotheses, I think I may go so far as to call them theories, of my own, which I formulated nearly a quarter of a century ago, and which have received, as far as I know, no attention at all, though both are of immediate practical importance. For some reason or other no one takes my doctrines seriously; at any rate, until they are adopted by some German, and are reintroduced into this country as made in Germany.

Characters of Germ and Sperm Cells.

My first proposition is this: Setting aside parthenogenesis, the alleged cases of which that come before the physician being found on investigation to be mythical, all reproduction is due to the union of a male element with a female element—of a sperm cell with a germ cell. My hypothesis is that the contributions of these two elements to the product differ in this way: the female element contributes the substance or matter of the offspring; the male element contributes the force or energy that animates the matter. The female element is the coals in the grate; the male element is the match that sets them alight. The female element is the great mass of dough in the kneading-trough; the male element is the little bit of yeast that leavens the whole lump and sets it all fermenting. The evidence in favour of this view seems to me overwhelming. In the first place, the disparity in bulk of the two elements is very great. The egg cell is of appreciable magnitude. In many organisms it is even visible to the naked eye. The sperm cell is excessively minute. In some cases the disparity is as great as 100,000 to 1. In the beginning and from the beginning, therefore, the female element does, in fact, contribute substance or matter out of all proportion to the amount contributed by the male. In the second place, the female element is lethargic and non-locomotor. It has no power of spontaneous movement, or even of change of shape. The only evidence of life that it gives is the preservation of its structural integrity, which is but brief, and its growth, which soon comes to an end. Its part is vegetative—anabolic. The sperm cell is the very opposite of this. It is extraordinarily active. It is rapidly locomotor. It incessantly changes its shape Its life, which is prolonged, is one of eager, strenuous, and incessant activity. It is the very embodiment of energy.

The Developmental Impetus given by the Sperm Cell.

Now note the result of their union. Before it is fertilised, or as I should rather say energised, by the sperm cell, the germ cell has an inert and vegetative existence. As it is alive, it must contain some stored energy or motion, for this is the character of all living things, but the motion that it contains is potential only, and is consumed internally in making and conserving additions to its bulk. Very rarely does the mammalian ovum even undergo a single segmentation or division previous to impregnation, and if left unimpregnated it soon dies, and dies, I suggest, because the amount of motion it contains is insufficient to hold the mass in equilibrium against the action of incident forces. It dies for the same reason that a top falls when it ceases to spin But now what happens when the minute mass of the sperm cell—a mass altogether insignificant in proportion to that of the ovum—is incorporated in its substance? At once the whole mass is infused with energy. It becomes the seat of active and incessant change. It segments and resegments incalculably. It receives, in short, an impetus that carries it forward for years upon the path of growth and of development. It is this view of conception, that regards it as the reception by the germ of an impetus to growth and development, that is so important and so fertile in the field of mental pathology. I do not deny that the germ contains within itself its own potentiality of development any more than I deny that the mass of coal in the grate contains its own potentiality of burning. Nor do I deny that the speck of matter in the sperm cell contains its own potentiality of indefinite multiplication, so that it may permeate the whole bulk of the organism, however many million times that organism may increase in bulk. I do not deny this any more than I deny that the grain or two of yeast may multiply so as to permeate the sponge in every part. And both the potentiality of the germ to develop and that of the sperm to multiply are important; but the supreme, the vital, the central fact in conception is the impetus given by the sperm to the germ, an impetus that carries the product along the path of growth to adulthood and maturity, and along the path of development until its gradual failure marks the onset of senility. It is this tremendous impetus that matters to the physician for mental disease.

The Implications of the Doctrine.

For note the implications of this doctrine and see how important they are. If you kick a football, or strike a billiard ball with the cue, or a cricket ball with the bat, you give that ball an impulse. You communicate to it an impetus. You send it flying along a path that is predetermined by the conditions. Now, this is the important thing—the distance the ball travels depends, other things being equal, upon the impetus that you communicate to it If you hit it hard it will go far; if you hit it less hard it will go less far. It is the same with the developmental impetus that is given to the germ at conception. If the impetus is a powerful one, the germ will travel far upon the predetermined path of development and growth; if the impetus is less powerful, the germ will travel less far. If the impulse communicated by the sperm is sufficiently powerful, it will make a boundary—it will reach the boundary of the normal. If it gets a tremendous swipe, it will go far over the boundary and become the lost ball of genius. If the impulse it receives is deficient in vigour, it will not reach the boundary, but will fall short of it by a space that will be greater or less according as the impulse is more or less lacking in vigour. The impulse may expend itself in reaching early childhood, or it may suffice to attain late childhood, youth, or adolescence, and according as the development of the brain ceases at one or other of these stages, the result is idiocy, or imbecility, or feeblemindedness, or mere dulness, as the case may be.

Two important qualifications must be made here. In the first place, insufficiency of the developmental impetus is not the only cause of deficiency of mind; in the second, deficiency of mind is not the only result of a defective conceptual impetus. Original deficiency of mind, of whatever degree, from idiocy to dulness, always arises from premature cessation of the development of the brain. This needs no demonstration. It is manifest on the face of the facts. But premature cessation of development may be brought about in two ways. When a cricket ball is driven by the bat it sometimes fails to reach the boundary, and the reason it does not reach the boundary may be that it was not driven hard enough; but it may be that it was driven hard enough, but on its way to the boundary it came in contact with some obstacle, say the hand, or the head, or the abdomen of a fielder, and its course was thus brought to an abrupt termination. Similarly, the development of the brain may cease from premature exhaustion of the developmental impetus, or it may be brought to a more or less sudden close by the intervention of some external agent which forcibly arrests it; and each of these methods is answerable for some cases of mental defect. The accidental intervention which puts a stop to the development of the brain may be a violent blow on the head, or it may be an inflammation of the membranes, or it may be the poison of some specific fever. All these may be said to have been proved by specific instances, but it is clear also that for a full development of the brain it must have an adequate supply of appropriate nourishment; and it is possible, and even probable, that some addition is made to the ranks of the mentally defective by those who are seriously underfed at the time the brain is actively developing. I say seriously underfed, for there is some evidence that the brain is not only greedy but masterful, and that it addresses to the rest of the body that straightforward and downright Dunstable maxim which we may term eutrophic, and which might well be written over the doors of the Chancellor of the Exchequer: "Thou shalt want ere I want." And I say underfed during the time the brain is actively developing because, although the brain goes on developing in some respects until it begins to deteriorate, its development does not proceed continuously. It goes by fits and starts; and this brings me to my second doctrine, which, like the rest of my teaching, has but a single adherent.

DIRECTION OF DEVELOPMENTAL IMPETUS INTO TWO CHANNELS.

The doctrine is this: that after a certain primitive stage of development is reached, it proceeds in two paths, which are complementary to one another, and to some extent inversely proportional to each other. However great the developmental impetus may originally have been, it is limited in amount; and if it is directed into two channels, then the more that flows into one channel the less there is at the service of the other. Those of you whose houses are still lighted by gas will know that at certain hours the gas, which had been burning quietly and steadily, begins to flare and sing, and you account for the change when you remember that at that hour the public-houses close, and a large expenditure of gas is suddenly shut off, leaving an increased pressure at the service of those who are still using it. There is another illustration that I am in the habit of giving. Everyone now knows that gardeners sometimes grow fruit trees consisting of but two stems growing from a single stock. These two stems or branches are fed from a single source of nourishment, which is limited in amount, and it is clear that the more that is attracted to one stem the less there is at the service of the other. Gardeners know of several expedients by which the flow of sap may be regulated and equalised so that neither branch shall grow at the expense of the other. Now if you carry this notion in your minds you will see what I mean when I speak of mere growth in bulk and of development in complexity being complementary to one another, so that the one proceeds at the expense of the other. The more of the developmental impetus or energy that goes to build up bulk of body, the less there remains to produce complexity of development, and *vice versâ*. Now the only organ that at birth is greatly wanting in complexity of development is the brain. All the rest are then almost complete, and thereafter grow in bulk alone, so that after birth the two great competitors for the single supply of developmental energy are bulk of body and complexity of brain; and complexity of brain stands roughly for development of intelligence. If the supply of energy is of average amount, and if it is shared in equable proportion between these rivals, the result will be a brain of average ability in a body of average size; but several modes of departure from this norm are possible, and are exemplified in experience.

Supposing the supply of energy to remain about the average, but the brain attracts more than its due share, the result will be exceptional ability in a person of less than average stature; and you will recall how many men of the highest intellectual eminence have been below the average height. I need only instance five of the greatest commanders in history—Cæsar, Marlborough, Nelson, Napoleon, and Wellington.

If, the supply of energy remaining normal, growth in bulk attracts an undue share, the result will be a brain of little power in a huge body; and it is notorious that giants are more often below the average in ability than persons of ordinary stature. They are not necessarily so, however, any more than dwarfs are necessary geniuses, for a clever giant may be produced by the equable distribution of an exceptionally large store of developmental energy, and an idiotic dwarf is quite frequent from what we may suppose is [illegible] to the developmental [illegible] taken place, but I have no doubt that the amount of this impetus can be materially modified by what takes place before conception, and there is no doubt that the proportions of it that go to increase of bulk and to development of intelligence respectively vary from time to time in the same person.

Precocious Children.

Hitherto I have spoken as if increase in bulk of body and increase in brain development proceeded equally and *pari passu*, but anyone who has watched the growth of children knows that this is rarely or never the case. Precocious children are common enough, and the precocious child is always small for his age; his brain has developed at the expense of his body. For a time the brain develops alone and growth in stature is stationary, and if this period is prolonged the child may become a marvel of precocity. One fond mother confided to me that she should give her child a special education to fit him for the only career that seemed worthy of his marvellous ability—that, namely, of Prime Minister. He was then 6 years old. Now he is the father of a family, and though of fair average business ability, he is not yet Prime Minister, and for my own part I should hesitate to entrust the destinies of the nation to his hands. His history is the history of scores of other precocious children. From five or six to seven or eight they are prodigies of learning and intellectual vigour. They are always top of their class in school, and they bring home prizes in heaps. But after a certain period of uninterrupted success at sc[illegible] are always small for th[illegible] Others, previously their [illegible] take them. They go down and down in the class lists until their parents' hopes are dashed, and even the medical man may be consulted to know if their brains are not giving way. But it is all right. The medical man, if he knows his business, will decide the matter by the measuring rod and the scales. He will notice that the child has begun to grow. He is shooting up by leaps and bounds. His trousers are too short, and his wrists project from his sleeves. By some means, perhaps by the product of some ductless gland, the developmental energy has been switched off from his brain and switched on to his body. Either there is not enough to serve both at once, or the regulating apparatus acts alternately, now one channel being opened and the other shut, and now the conditions being reversed. After a period in which growth proceeds apace, and intelligence seems actually to diminish, the conditions are either reversed again, or more often a better balance is established, and the two proceed together in harmony; but children who have been violently precocious never, in my experience, completely recover the check to growth in stature that they receive during their precocity.

Practical Conclusions.

[illegible] consequences follow. In [illegible]ecocious it is never safe to [illegible]nes on fire. I say nothing about musical prodigies or calculating prodigies, because music and mathematics, like chess, and linguistics, and certain other faculties, have no relation to general ability. They may be highly developed in the dull, and they may be absent in exceptionally clever men. They go for nothing. In the second place, when a hitherto intelligent child becomes stupid, dull, clumsy, and even when it exhibits mental traits that are distinctly abnormal and alarming, we need not be much concerned if we find that it has started into rapid growth; and if the growth is very rapid almost any mental symptom may be witnessed without alarm. In the third place, we need not fear ill results from stimulating the intelligence of a child, even of a precocious child, provided it is healthy in body, eats well, sleeps well, and is not disturbed by dreams, and provided we do not [illegible] the period w[illegible] grow[illegible] of mind. [illegible] growth about 20 per cent. of epileptics, and in the majority of these there were more salient symptoms of the disorder. In four instances the epileptic attack towards its termination presented all the features of an hysterical crisis. In eight cases the epileptic and hysterical fits in the same individual occurred independently. In the majority of the other cases—12—besides the stigmata pointing to hysteria were such symptoms as neuralgic pains, headaches not connected with fits, palpitation, sleeplessness, vivid dreams, tremor, and pain over the heart.

Certain of the hysterical stigmata were found in 25 out of 96 cases of Sydenham's chorea, and in many some more pronounced features of the disease were also present. Together with the incoördinate movements of chorea, there were such manifestations as rhythmical spasm of an arm, rhythmical twitching of the eyelids, regular clonic movements of the legs, and rigidity of the legs. In one case hysterical rhythmical spasm followed chorea after an interval of two days, and in another in the course of two months. In two other instances the chorea was not of the ordinary type, and seemed to be a hysterical or subconscious renewal of former attacks of genuine chorea. In the remainder of the 25 cases there were such symptoms as neuralgic pains and tender spots in 10, vomiting without apparent cause in 2, aphonia in 2, semi-hysterical attacks in 4, typical hysterical cough in 1. To emphasise the distinction between ordinary and the so-called hysterical chorea several tracings were exhibited of rhythmical tremor and spasm.

The infective diseases, continued Professor Glynn, may provoke hysteria, and the affection may complicate their progress as well as follow during convalescence. Cases of rheumatic fever and typhoid associated with hysteria were referred to. Chlorosis for obvious reasons was, he said, very frequently attended with hysteria. Out of 164 cases of chlorosis, 45, or 25 per cent., were hysterical. In 20 out of the 45 there was much headache, as a rule vertical, with restlessness at night and vivid dreaming. Eighteen suffered more or less from obstinate vomiting and gastralgia, 5 had hysterical fits in some form, 8 exhibited fine tremor of the hands, 4 complained of pain and tenderness over some part of the spine, and 3 of great weakness of the legs. Two developed hysterical anorexia.

In Graves's disease the hysterical stigmata were present in 35 per cent.

There was evidence of hysteria in the presence of the stigmata and in a few of other symptoms, in three-fourths of the cases of simple gastralgia in young women. It was not likely that the hysteria was only accidentally associated with the gastralgia, since they were found together in so many instances; moreover, the hyperæsthesias and pains are just as characteristic a feature of hysteria as are the anæsthesias.

He had met with 15 cases of anorexia nervosa, and in each of these certain hysterical stigmata were present. One subject of the disease became comatose and was measured for her coffin, but under vigorous treatment recovered. Two died, one was removed to a nursing home when hopelessly weak and the other recovered for a while but in 12 months relapsed and died. Another case was very exceptional, the subject of the disorder being a boy.

The hysterical stigmata were present in 23 per cent. of the cases of gastric ulcer in young women, that is in patients with a history of hæmatemesis or melæna.

The relation of hysteria to heart disease was of special interest. Such hysterical affections as pseudo-angina, or simple pain over the heart, palpitation, dyspnœa, and syncope, when the heart is normal arouse fears of cardiac disease in the patient, and worry the medical attendant till he lights on the explanation of the symptoms, and when these hysterical accidents occur in cases where there are signs of organic heart disease they are likely to cause the patient's condition to appear more serious than it is. Further, as nervousness, sleeplessness, and pain are usually associated with hysteria the symptoms due to heart disease tend to be aggravated. Several cases were referred to in illustration. One was a girl with mitral stenosis who after a faint lost the power of her left arm; the paralysis proved to be hysterical in nature and not due to cerebral embolism.

In conclusion, Professor Glynn discussed the alliance between hysteria and the functional and organic diseases of the nervous system.

ON THE STATE OF THE BLOOD-VESSELS IN SHOCK.

BY JOHN D. MALCOLM, F.R.C.S. EDIN.,

SENIOR SURGEON TO THE SAMARITAN FREE HOSPITAL, LONDON.

IN 1893 I published[1] my belief that in cases of fever, of post-operative intestinal obstruction, and of traumatic shock there is a contraction of the arteries extending from the arterioles to the larger vessels and progressing until the causal conditions are removed or the patient is moribund. That view was opposed to the teaching of the day that the vessels of the splanchnic area become paralysed in the state of shock and it has also been urged from time to time[2] against the theory that the vessels throughout the body become relaxed. This last theory has for the past six or eight years been almost universally accepted, but recently its accuracy has been less assured, and at the Seventeenth International Congress of Medicine, in the debate on the Pathology of Shock,[3] not one speaker suggested that the arteries are relaxed or dilated in that condition.

The time, therefore, seems opportune for a review of the evidence on this subject, and I propose to state again very shortly the chief points in the argument in favour of the contention that the arteries contract as shock develops, and to indicate some of the more recent facts which have been brought forward in relation to this question. I give precedence to the clinical evidence because it constitutes my justification for offering an opinion and because the value of laboratory work to the surgeon must in the long run be judged by its success in explaining clinical conditions.

Clinical Considerations.

When in the course of an operation a patient passes into the state of shock, even if he loses little or no blood directly from divided structures, his tissues become obviously more and more bloodless, and careful observation during operations upon the abdomen shows that the anæmia is as conspicuous in the splanchnic area as in any other. This observation has been confirmed by Dr. G. W. Crile[4] who wrote concerning his laboratory work that both before and after death from shock "the arteries were quite empty, the tissues pale." He also said that when the splanchnic area was not involved in the manipulations of an experiment "autopsies did not reveal a condition of vascular distension in this area different from that of other areas."[5] Unless these observations are altogether mistaken, it is certain that there is no dilatation of the vessels generally or of those in the splanchnic area alone in the state of shock.

During the progress of severe operations it may occasionally be observed that the arteries become imperceptible at the wrist whilst the pulse-rate is not quickened or even is slower, and the beats of the carotid are full and bounding. On one occasion it was noted that at the end of an operation upon a healthy young woman the pulse-rate was 48 to the minute, and no pulsation was perceptible in any vessel of the extremities. The operation, an ovariotomy, was not a severe one, and the usual state of the vessels was restored after a very short time. A similar combination of signs was frequently observed passing gradually back to the normal or developing into the rapid heart action which is characteristic of well-marked cases of shock.

Such conditions could only arise from an increased opposition to the flow of blood through the small vessels and a well-sustained output of blood from the heart. The dissociation for a time of the small, weak, or imperceptible pulse from the hastening of the heart beats which usually accompanies it suggested that the arterial contraction was the more constant change. It did not seem possible that in some cases the arteries could be contracted whilst in others they were relaxed, or that in the particular cases now under discussion the active contraction which certainly occurred could become a relaxation without some sign of the gradual or sudden change. If the change was gradual the pulse at the wrist would come back to its ordinary volume if only for a short time, a condition never observed during the development of shock. If contraction of the vessels suddenly became relaxation there would certainly be some acute disturbance which could not be overlooked clinically. As there were no signs of any such changes, there could be no doubt that the contracted vessels did not relax.

All authorities agree that the heart is stimulated to greater effort as shock develops and there seemed to me to be much reason for believing that the slow heart action associated with a small or imperceptible peripheral pulse might be observed more readily, if not only, in cases in which the heart muscle was relatively strong. When these observations were made the work at the Samaritan Free Hospital consisted in great part of the removal of large ovarian tumours, and it seems probable that such cases offered unusual opportunities for the observation of the effects of a comparatively powerful heart. It is well known that cardiac hypertrophy is a physiological effect of gestation, and it is reasonable to suppose that the presence of an ovarian tumour would at least occasionally induce a similar change. This view was supported by the fact that in a few cases an opportunity was obtained of examining the heart at a necropsy when its action had for a time remained slow after the pulse at the wrist became very small or imperceptible, and in these cases the cardiac muscle was always well developed, whilst in one instance there was a very obvious cardiac hypertrophy without any gross cardiac or renal lesion or other discovered cause of this condition except the presence of the tumour. The facts recorded led me to assert in 1893 that "if the heart be sufficiently strong its action remains slow,"[6] but that if still greater contraction of the vessels takes place the heart becomes relatively feeble and its pace quickens.

The extreme pallor in all the tissues, the definite evidence that in some cases the arteries were tensely contracted whilst the heart action was not hastened, the known fact that stimulation of the sensory nerves causes arterial contraction, and many other observations which cannot be set down in a short paper, were considered together to form a proof that "in traumatic fever, in shock and in abdominal distension following a laparotomy, the small feeble pulse, whether slow or fast, is in no sense due to cardiac weakness, is not a condition beginning at the heart, but is an immediate effect of the contraction of the vessels."[7]

If these contentions were true it was certain that the total volume of blood in the arteries must diminish, and in the absence of any marked venous distension it was argued that the fluid parts of the blood must escape from the vessels into the tissues. In cases of intestinal obstruction after abdominal operations, in which also it was held that the vascular capacity steadily diminished, there was no doubt that a great loss of fluid from the body did occur, because this condition is characterised by an extreme degree of exudation of fluid into the intestine and out of the body by vomiting. Moreover, in this condition the vomited fluid is at first clear, and gradually becomes yellow, green, brown, and nearly black. These changes indicate that not only fluid escapes from the vessels, but that there is also an excessive and increasing destruction of blood cells in the liver. In the state of shock there is little time for such obvious indications of blood destruction to show themselves, and it does not follow that an excessive secretion of bile of short duration will be ejected from the stomach through the œsophagus, but sometimes recovery from shock is accompanied by vomiting of bilious or even black fluid, and the amount of fluid lost from the skin is always great when the condition is well marked.

The loss of fluid and other constituents of the blood from the vessels was regarded as the cause of the extreme anæmia of the whole body, and death was attributed to a starvation of the various tissues and organs which might be traced in the evidences of the failure of their functions. When the vaso-motor centres were affected the whole body died.

Experimental Considerations.

A short *résumé* of the experimental evidence shows that it is conclusive in support of the clinical. The theory that in shock the animal bleeds into its own splanchnic veins has now no supporters. Dr. G. W. Crile's first book advocating the view that shock is characterised by a general vascular relaxation was published in 1899,[8] and in that year also Romberg and Pässler[9] advanced the same view on very much the same grounds with regard to the conditions found in toxæmic fevers. In regard to both shock and toxæmic fevers it was argued that death was not due to cardiac failure, as was then generally believed, but that there arose a loss of tone in the vaso-motor system followed by a failure of the circulation when the vessels relaxed. This view had a great vogue as regards shock until quite recently. Romberg and Pässler's communication did not apparently attract so much attention.

The argument depended entirely upon the interpretation of the fall of blood pressure. It has long been known that a stimulation of sensory nerves excites reflexly a general arterial contraction and a consequent rise of blood pressure in the large arteries. Conversely a relaxation of the vessels lowers blood pressure in the large arteries. It was shown in 1899 that if the stimulations of tissue were sufficiently severe or if fever was sufficiently continuous the blood pressure after a rise fell very low, and this was regarded as a proof that arterial relaxation had occurred. It was argued that the fall of the pressure became so great that when the state of shock was fully established the vessels were completely relaxed, and this condition was attributed to a paralysis of the vaso-motor centres from over-stimulation and consequent exhaustion of their energy. But this argument omitted altogether the possibility that the volume of blood in the vascular system might diminish and the obvious fact that the tissues became anæmic both in shock and in fever. As Yandell Henderson has pointed out, the conclusion that the vessels relaxed was arrived at because the authors of this view "applied to their problem that conception of the circulation which the physiology of to-day teaches. This was their sole mistake."[10] Many new facts were demonstrated by detailed records of most interesting experimental work, and none of these facts have been contradicted in any material respect, but the evidence is now very strong that the interpretation was at fault. As early as 1903 physiologists began to question the evidence that the vaso-motor centres become paralysed. In that year Professor W. T. Porter and Dr. W. C. Quinby, of the Harvard Medical School, published experiments showing that in the state of shock the vessels were still influenced reflexly by nerve stimulations, and they concluded that "exhaustion of the vaso-constrictor nerves cannot therefore be the essential cause of the symptoms termed 'shock.'"[11]

In 1907 Professor Porter recorded another "investigation into the effect of uniform stimulations of the depressor brachial and sciatic nerves at various levels of blood pressure from the normal down to about 9 mm."[12] of mercury. He showed that "the absolute change in blood pressure upon stimulating these afferent nerves remains almost unchanged until the blood pressure has fallen to about one-third its usual height,[13] and that "the reflex fails only when the blood pressure sinks to a level at which anæmia of the vaso-motor centres is certain. Indeed, all we know regarding these and similar cells strengthens the belief that their endurance under stimulation is very great. On the other hand, they are extraordinarily sensitive to changes in the blood-supply." It was added that "the data presented are wholly opposed to the hypothesis that would explain surgical shock by the exhaustion of the vaso-motor centres."[14]

The question of the state of the vessels in shock was also studied by Dr. M. G. Seelig and Professor E. P. Lyon, of Saint Louis, Mo., U.S.A.,[15] who performed an ingenious experiment upon a series of dogs showing that division of the sciatic nerve made a greater proportional increase of the blood flow from the previously divided femoral vein in a shocked animal than the increase observed in the other leg of the same animal before the state of shock was brought about. The deduction was drawn that "this proportional difference must be referred to the fact that in the shocked animal, before division of the sciatic the vessels are in a state of greater contraction than they are in the normal animal." The authors of these observations invited Dr. John Green, jun., to examine the eyes of dogs before and after the induction of shock, and to note carefully the size of the vessels of the fundus without telling him what was or was not expected. "In every instance he reported that the vessels showed a marked degree of contraction after the animal was in shock." Sometimes the vessels resembled mere threads, and in one case the contraction was observed immediately before the animal died.

Dr. Eugene Boise holds that the chief cause of the fall of blood pressure in shock is an abnormal increase in cardiac contraction and a decrease of cardiac relaxation by which the capacity of the heart becomes so reduced that it cannot adequately fulfil its propelling functions. From an analysis of Crile's records and from his own investigations Boise argued that in shock "there is an excessive irritation of both the vascular and cardiac centres whereby the arteries and heart are both almost spasmodically contracted."[16]

Professor Yandell Henderson, of Yale University, U.S.A., has formulated a very large conception regarding the effects of diminution of the quantity of CO_2 in the tissues. His views are in many respects altogether original, and they seem to me to throw a flood of light upon conditions about which we have hitherto been quite in the dark. Haldane and Priestley had confirmed[17] the observation of Miescher that variations in the amount of CO_2 in the body are very important and had shown that very slight differences of the pressure of this gas in the pulmonary alveoli (normally about 5·5 per cent. of an atmosphere) lead to an immediate hastening or slowing of the respiration until the normal tension is readjusted.

Mosso had demonstrated[18] that under reduced atmospheric pressure the CO_2 content of the blood is diminished and that this diminution is one of the causes of the disturbance of function in mountain sickness. He suggested the term acapnia (α, privative, and καπνός, smoke) for this diminished pressure of CO_2.

Following up these indications Henderson worked out his scheme and he has summarised his views thus.[19]

> From the data to be presented in this series[20] of papers it appears that the CO_2 content of the blood exercises regulating influences upon the heart rate, upon vascular tonus, upon the peristalsis of the alimentary canal, upon the mental condition and upon a number of other functions of the body to a degree so far as we can find from the literature, hitherto in great part not demonstrated. These data show that even a slight reduction in the CO_2 content of the arterial blood causes a marked quickening of the heart rate. Further reduction induces an extreme tachycardia, complete cessation of peristalsis, failure of many reflexes and coma. If an extreme reduction of the CO_2 content of the blood is effected very rapidly the heart comes into a state bordering on tetanus. This cardiac tetanus practically abolishes the pumping action of the heart, arterial pressure falls therefore, and death results.
>
> If the reduction in the arterial CO_2 is less extreme, but is maintained for a considerable time (an hour or more according to the extent of the reduction), so that the tension of CO_2 in the venous blood and in the tissues is greatly reduced, symptoms and conditions result which are similar in many respects to those occurring in mountain sickness and apparently identical with those of shock.

Henderson says that "acute acapnia diminishes the volume of the blood as effectively as does an extensive hæmorrhage,"[21] and that "arterial pressure ultimately sinks in spite of an intense activity (not because of failure) in the vaso-motor nervous system, and in spite of an extreme constriction (not because of relaxation) of the arterioles."[22]

The influence of a subnormal amount of CO_2 in the tissues has been investigated also by Dr. E. Jerusalem and Professor E. H. Starling of University College, London, who state that their experiments[23] confirm Yandell Henderson "in his description of the action of the heart when the CO_2 of the blood is reduced to very low limits."

Thus from many independent sources there is an overwhelming mass of experimental evidence, and much more could be quoted, to the effect that the heart and the vessels are both stimulated to increased activity as the state of traumatic shock develops.

But Yandell Henderson's scheme involves a much wider area than the vascular changes in shock. He says that acapnia has been found "in many forms of fever, in diabetic coma, in the conditions consequent on violent muscular exercise, and in that form of shock which results from the intravenous injection of albumose and 'peptone.' In all of these conditions, as well as in mountain sickness, excessive artificial respiration, and surgical shock, there occur at one stage or another, and in varying order, hyperpnœa followed by shallow respiration or apnœa, tachycardia, venous congestion, and fall of arterial pressure, muscular weakness, suppression of reflexes, disturbances of consciousness and disturbances of the motor functions of the alimentary canal."[24]

It is impossible in a short paper to attempt to give any adequate account of Yandell Henderson's teaching, but it seems to be in complete accord with my contention mentioned at the beginning of this paper, that in cases of fever, of post-operative intestinal obstruction, and of traumatic shock there is a persistent and increasing contraction of the arteries, a conclusion which I believe to be demonstrable at the bedside.

These very short remarks indicate with as little detail as possible the views of the state of the vessels in shock which seem to me to be supported by the clinical and experimental facts set forth. The matter is obviously of great importance, for if it is a mistake to believe that the vessels relax as a consequence of severe or continuous injuries it is hardly likely that much real progress can be made in the study of operative conditions until that mistake is rectified. The opposite view that the vessels contract offers a much more certain guide both for understanding and treating the conditions found. And as regards the detail that in fevers and in shock the same vascular changes take place, I am convinced that this fact, as I believe it to be, gives an immense advantage in understanding clinical phenomena to those who accept it.

Wimpole-street, W.

FOURTH REPORT ON TYPHOID CARRIERS.

BY D. S. DAVIES, M.D. LOND., LL.D., D.P.H.,
MEDICAL OFFICER OF HEALTH OF BRISTOL;
AND
I. WALKER HALL, M.D. VICT.,
PROFESSOR OF PATHOLOGY, BRISTOL UNIVERSITY, AND PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY.

With the Assistance of G. SCOTT WILLIAMSON, L.R.C.P. & S. Edin., L.F.P.S. Glasg., *Pathologist to the Bristol General Hospital;* and B. A. I. PETERS, B.A., M.D., D.P.H. Cantab., *Resident Medical Officer, Ham Green Hospital, Bristol.*

IN the last report[1] it was concluded that the results then obtained justified a prolonged study of the case in hand. The present note deals with the further course of the condition.

The methods employed are the same as were detailed in former communications. For reasons previously stated the examinations have been limited to the search for typhoid bacilli in the excreta, the determination of the agglutinin contents of the serum, and the action of therapeutic agents.

The carrier was a female, aged 33, who had enteric fever in July, 1905. Since that date eight cases of infection had been traced to her. She came under observation in January, 1909, and proved to be a urinary carrier. For a period of three months urotropine was given continuously. The excretion of typhoid organisms in the urine was decreased but not inhibited entirely. On April 21st, 1909, a bacillary emulsion prepared from the patient's own organism was given. The doses were continued until 1000 millions were reached. The injections were discontinued on Sept. 29th,

1909 *From October, 1909, to January, 1910, typhoid* bacilli were not excreted in the urine On Jan 4th they reappeared and persisted until Feb 27th During this period the agglutination reactions varied from 1 1000 to 1 1800 Potassium citrate was given for three weeks There was a cessation of the bacillary excretion until the following July

Fourth Report

The observations now recorded show that the urine of this patient has remained free from typhoid bacilli for two years We feel justified in recommending the discharge of the patient from hospital, subject to her promise to report herself should any of her former symptoms reappear, or for additional treatment if current experimental investigations upon the adjuvant action of drugs or metals upon typhoid bacilli prove worthy of trial in similar conditions

On Nov 1st, 1910, the patient was removed from the Ham Green fever hospital to the Bristol Royal Infirmary and placed under the care of Dr J A Nixon Her temperature was normal and her general systemic condition good On the 7th a cystoscopic examination was made by Mr C F Walters He states —

> The bladder was found to be normal except at the right ureteric orifice the lips of which were markedly *œdematous and superficially*
> [illegible] was an area of trabeculation
> [illegible] difficult owing to the œdema
> [illegible] 1½ inches only here there was
> [illegible]

The urine obtained from the right ureter contained much pus and yielded a pure growth of typhoid bacilli The left ureter was catheterised with ease, and the urine was free from pus and typhoid bacilli A skiagram was taken, it showed a shadow in the region of the right kidney On the 21st Mr Walters explored the right kidney To the naked eye it did not show any abscesses cysts, or contractions When bisected longitudinally during a search for foci of suppuration ten small calculi were found lying in one mass near the pelvis The calculi were removed the cavity was scraped, and the kidney sutured and returned into the body The renal cavity yielded a pure growth of typhoid bacilli Typhoid bacilli were isolated from the calculi also The calculi were composed of phosphates and organic material only At noon on the next day the temperature commenced to rise, reached its highest point (104 2° F) on the 24th and then fell [illegible] normal on Dec 1st A slight [illegible] recovery was uneventful [illegible] reached and remained at 1 1500 On the day following the operation bacillus *typhosus was grown from 5 c c of blood obtained in the* usual way Pus and typhoid bacilli were found in the urine during the first four days after the operation the agglutination reaction being positive 1 1000 During the following fortnight the typhoid organisms disappeared from the urine and the agglutination fell to 1 250 Pus and bacilli then reappeared and persisted for the next eight months

Comparing the clinical features of the case at the time with those of Rousing,[2] Greaves[3] and Adrian, and Meyer and Ahreimer[4] the condition was less advanced as there was not any definite pyonephrosis, nor were there any signs of a marked renal involvement, such as acute localised pain or difficulties with micturition At the operation the renal pelvis did not appear to be affected However, the changes in the right ureter were of long standing, so that the pelvic mucosa most probably shared in the *ureteral focus* The *bladder remained free from superficial* changes

The rise of temperature subsequent to the operation and the concomitant appearance of typhoid bacilli in the blood stream as well as in the later increase in the agglutinin content suggest that a mild septicæmic condition was brought about by the disturbance of the focus The chart on next page [illegible] were rapidly overcome We [illegible] as to the occurrence of any [illegible] his invasion Had the immunity been low or the organisms of exalted virulence such a result might have been produced

Course of Bacteriuria —Onwards from the operation the typhoid organisms and pus were present in the urine On

Temperature chart for the days following operation.

March 4th, 1911, therefore, it was decided to give the patient one drachm of borovertin daily. This was continued until May 24th, when it was stopped, because the patient complained of being "run down." During this period of administration of the borovertin she lost 7 lb. in weight. When the drug was discontinued recovery to her usual condition was rapid. On July 31st she had regained her average weight. Borovertin was then recommenced and given in the same doses until Sept. 2nd. The weight again fell 5 lb. During these courses of borovertin the excretion of bacilli was unaltered. On reference to Table I. it will be seen that pus and bacilli were present in the urine throughout.

Course of specially prepared Bacterial Emulsion.—On July 1st, 1911, the blood yielded a typhoid organism which was agglutinated by the patient's own blood in 1:500, and after three weeks' cultivation 1 : 800. Cultures of this organism and of a subculture from the urine were repeatedly subcultured for three weeks on (1) serum agar, (2) blood agar prepared with the patient's own blood, and (3) carbolic acid agar (1:10,000 gradually increasing to 1:500). At the end of the three weeks a bacterial emulsion was prepared from a mixture of the growths on the several media and injected.

Table I. shows that the urine ceased to contain pus and typhoid bacilli during October, 1911, while the agglutinating power of the blood rose to 1/2500. The systematic examinations carried out since then until July 23rd, 1913, have failed to reveal any further excretions of the organisms, while the agglutination titre has fallen to 1/150.

TABLE II.—*Injections of Bacterial Emulsion.*

Date.	—	Remarks.

" 5th.	400,000,000	—
" 6th.	800,000,000	Giddiness and malaise were complained of. There was also slight pyrexia.
" 23rd.	1,600,000,000	—
" 27th.	3,200,000,000	—
Oct. 1st.	6,400,000,000	Giddiness and sickness. Pyrexia. Compelled to remain in bed for three days.

Blood cultures.—The blood has been examined during the periods of bacillary excretion. On four occasions it has been found sterile; twice it has yielded a strain of bacillus typhosus which was agglutinated 1:500 by the patient's own serum, the agglutination reaching 1:800 after repeated subcultures during three weeks.

Inhibitory power of urine.[5]—Table III. shows the inhibiting power of the patient's urine upon various micro organisms The effect was not obtained when the urine was boiled before being added to the emulsions. Exposure of the urine to strong sunlight did not alter the inhibitory power. Normal and carrier urines were filtered through a Chamberland candle. 0·1 c c. of urine and 0·1 c.c. of an emulsion containing 10 millions of B. coli, B. typhosus (the various strains being denoted by the letters A, B, C) or staphylococci, were incubated for 1–2 hours, and then shaken and sown upon lactose litmus agar plates. After 48 hours at 37° C. the resultant colonies were counted.

TABLE III.—*Showing the Inhibitory Power of the Urine upon Various Micro-Organisms.*

Date.	Urine quantity.	Normal urine, number of colonies per plate.	Carrier's urine, number of colonies per plate.	Bacterial strains.
1911.				
May 2nd.	0 1 c.c.	64	3	B. coli A.
		34	0	B. coli B.
		111	13	B. coli C.
		34	41	Staphylococci.
		108	0	B. typhosus A.
		77	15	B. typhosus B.
		210	34	B. typhosus C.
August 17th.	0·1 c.c.	100	6	B. coli.
		32	0	B. typhosus.
		19	33	Staphylococci.

On the above dates typhoid bacilli were not found in the urine. The carrier urine did not inhibit the growth of staphylococci, but exerted a marked effect upon the typhoid-coli group.

The evidence of tissue reaction.—The agglutinin content of the blood has been determined at intervals and in periods of about four days each. The method followed was that adopted with the object of obtaining comparative results.[6] Table I. shows the high content at the time of the operation and the slow but gradual fall since the cessation of the special vaccine injections. There is still, however, a considerable agglutinative power. Whether this is due to a "habit," or arises from the stimulation of some latent focus, time alone can tell.

Condition of the bladder and ureter in September, 1913.—On Sept. 23rd a further cystoscopic examination was made by Mr. Walters. "The bladder," he says, "was found to be normal in appearance, no trabeculation was visible, and all signs of inflammation had disappeared from the right ureteric orifice."

This patient has now been under our continuous observation for four and a half years. Like other carriers of the urinary type, she has exhibited "intermittent" periods. These have varied from a few days to a few weeks. One of them, however, extended to eight months (April, 1909, to January, 1910) Since August, 1911, we have not been able to demonstrate the presence of typhoid organisms in the urine. The routine practice during this time has been to centrifugalise 15 c c. of urine and to use the whole of the deposit for enrichment methods prior to plating out. The quantity has been increased to 100–200 c c. whenever the microscopical appearances of the deposit were at all suspicious. Throughout the whole course of the case bacillus coli has been present occasionally. Sometimes these organisms were associated with a small amount of pus: more frequently there was not any evidence of reaction For six months the latter condition has prevailed

---

[5] These experiments were carried out by G. S. W.

[6] THE LANCET, Sept. 3rd. 1910, p. 723.

It is perhaps well to state clearly that we do not claim that the typhoid latency has entirely disappeared The agglutination reactions, in the light of earlier appearances, do not permit of such a contention Still the comparatively sudden cessation of the bacillary excretion the concomitant rise in the tissue reaction and the subsequent freedom from symptoms, &c, *lead us to hope that such a result may be* possible We intend to continue to make periodical examinations of the urine and to apply further medication when called for

The observations now recorded have been made possible by the action of the Public Health Committee of the Bristol Corporation in allowing the carrier to remain at the Ham Green fever hospital and by several grants towards the expenses of the laboratory investigations from the Bristol *University Colston Society's Research Fund* The patient herself has displayed a willing and intelligent coöperation throughout

DISEASES DUE TO DEFICIENCIES IN DIET[1]

By F GOWLAND HOPKINS M A CANTAB, M B, D SC LOND, F R S,
FELLOW OF TRINITY COLLEGE AND HONORARY FELLOW OF EMMANUEL COLLEGE CAMBRIDGE.

THE whole trend of modern pathology has made our minds ill prepared to believe in an extraneous deficiency as the prime cause of a specific disease We recognise perforce inherent deficiencies in the body of structure or material, but even these, when they are not anatomical and obvious, we tend *to look upon as for the most part only* predisposing or contributory, the essential and immediate cause of any disease we rather seek in the intrusion of some positive factor, some *res noxia*, be it parasite or poison So completely is this course justified in general that there is doubtless an excuse for the present tendency to seek for such an intruder in cases where there would seem to be little reason to expect its presence, as in certain diseases of nutrition

When disease is ascribed to diet the implication is nearly always that the food is infected or poisonous, or at any rate that some constituent is in such excess as to be deleterious Some malific factor of a positive sort is usually thought to be essential Even the pioneer in the work upon beri-beri, although his labours had given him the essential facts did not escape the effect of what seems a bias Eykman proved that the symptoms of beri beri followed upon the eating of polished rice and showed that the addition of the missing pericarp was curative, but he was constrained to hold, not the simple, and apparently obvious, view that the pericarp contained something necessary for normal metabolism, but that toxins developed in the endosperm, while a constituent of the pericarp was able to *neutralise them*

It is rather remarkable that neither physiologist nor pathologist rendered ready belief to the suggestion that among the dietetic needs of the animal might be organic substances small in amount and easily overlooked by the chemist The suggestion had been in the literature of nutrition experiments for many years but it was neglected Yet since the animal has always been adjusted to live directly or indirectly upon plant tissues, which contain countless substances other than proteins carbohydrates, and fats, there was no *a priori* reason to doubt that physiological evolution might have made some of these substances essential Yet had the fact been definitely established in the nutrition laboratory [illegible] interest *It might* [illegible] ant deficiency in s[illegible] dietaries It required such facts as those which have come to light in connexion with beri beri to establish a wide and practical interest in the matter The case of beri beri is, indeed, a very remarkable one The wide consumption by whole races of a one sided dietary, the localisation of a specific substance in a grain an artificial treatment of that grain exactly adjusted to remove the substance and the occurrence of prominent symptoms as a result of its removal—all these coincidences were necessary *to yield so* striking a proof that a disease may arise from a dietetic deficiency Without them it is unlikely that we should have been engaged in this discussion

Many of us believe that the establishment of this plain case may lead us to discover many others less obvious, and that a new chapter in the subject of animal nutrition is now opening It is only to be hoped that those who help to write the new chapter will display due caution The whole literature concerning the relations of food to health and disease is so flooded with baseless theories with fads and fancies, that it is well to see that no new channel shall be opened to them

I take it that to obtain satisfactory evidence that a specific diet deficiency is directly responsible for a given complex of symptoms it must be shown that the association between the suspected diet and the symptoms is sufficiently frequent, and the occurrence of the symptoms upon normal diet sufficiently rare, to satisfy the statistician, while to obtain rigid proof we must discover what the deficiency really is and prove that removing it results in prevention or cure of the symptoms

In defining our criteria I think it is justifiable to insist *upon the fact that the disease need not be wholly absent* from individuals using normal diets, but only sufficiently rare What is absent from a faulty dietary may be the necessary raw material for some particular metabolic process or some hormone which initiates the process In such a case all individuals consuming the dietary must sooner or later suffer from whatever is involved in the failure of that process But it is clear that in an occasional individual assimilation may be faulty, the apparatus in which the process occurs *may develop faults, or other factors necessary* to its continuance may fail The final result will then resemble that due to the absence of the raw material Our criterion must be this that the disease is absent from or[illegible] al dietary, but common am[illegible] ned to the diet under sus[illegible] the evidence that they have added nothing of significance to their diet is difficult to obtain, for all that we know at present about the subject suggests that very small additions may make all the difference to the results But any considerable degree of individual immunity would be evidence that the etiology of the disease involves some positive factor and not a deficiency alone In the case of beri beri and in that of scurvy we have *evidence which very nearly, if not entirely, satisfies* such criteria There is scarcely any doubt that they are diseases due to deficiencies of diet and to those alone The same cannot perhaps be said of any other specific disease

It is clear that in opening this discussion I can deal only very briefly with individual instances

Concerning beri beri I would like first to say that after reading all the descriptions I could find of cases which are supposed to have occurred under normal dietetic conditions I feel—without pretending to be an expert in matters of diagnosis—that the evidence they offer against the modern view is unimportant It is to be hoped that the question of its cogency will be discussed

The *present position of the beri beri question* is of particular interest because, owing to the brilliant work of Casimir Funk, we have considerable knowledge concerning the nature of the substance of which the deficiency is responsible for the disease We have not final knowledge, as Funk will probably be the first to admit I will venture to say that I myself am more impressed with the objective proof he has given us that the phenomena before us depend upon tangible substances than by the evidence he offers for the actual constitution of what he has so appropriately termed vitamines

In the case of scurvy the probability that a diet deficiency is an essential etiological factor has, of course been long forced upon the attention The remarkable thing is that the probable deficiency should have been so long discussed in terms of known substances It was so easy to prove that none of those suggested—potassium salts, citric acid and the like—had anything to do with the matter, and it was always clear that a substance so unstable and so easily lost from normal foodstuffs had to be looked for amid the unknown.

---

[1] Remarks introductory to a discussion in the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on Oct 21st, 1913

The work of Holst and his colleagues upon experimental scurvy, though it has not told us what antiscorbutic substances may be, has thrown much light upon their essential properties. Anyone who lacks conviction can easily learn how great may be the effect of small deficiencies in diet by repeating the observations of Holst and Fröhlich under rigid experimental conditions.

When we consider in particular acute infantile scurvy we find what seems to be the clearest evidence for the influence of a deficiency produced by the artificial treatment of milk, combined with much conflict of evidence as to the degree and kind of treatment which is capable of inducing the deficiency. This is a well-worn question, but there is some justification for saying a word or two about it. In discussing it I must refer again to the work of Holst and Fröhlich.

It should be noted first of all that the symptoms and post-mortem appearances exhibited by animals such as guinea-pigs after some weeks of a grain dietary are most strikingly similar, even in their details, to those found in Barlow's disease. Any one who has troubled to repeat the observations will hardly doubt that the etiology of the two conditions must be essentially the same. The main symptoms may develop in guinea-pigs in advance of any loss of weight, while, when similar animals are fed upon fresh vegetables the symptoms remain absent, even if the diet be insufficient and weight is rapidly lost. The condition is clearly no result of general malnutrition. After it is established giving fresh vegetables or vegetable juices gradually removes the symptoms, but if heated, dried, or long kept such materials lose there curative power. What is especially interesting in connexion with the point I am dealing with is the fact that in different foodstuffs the antiscorbutic substance exhibits varying degrees of stability, which may suggest either that it is not always the same or that varying conditions affect its stability. Fresh milk was shown by Fröhlich to have a definite antiscorbutic influence in guinea-pigs. Milk, in fact, contains both a substance inhibiting the induction of beri-beri symptoms and another which is antiscorbutic. They are not the same, as Funk has pointed out, since their stability towards heat is markedly different.

Now, it would seem from the results got in experimental scurvy that the temperature at which the antiscorbutic substances in milk are destroyed can be sharply defined, for Fröhlich found that after heating to 70° C. the milk used by him retained its preventive power, whereas ten minutes' exposure at 98° completely removed it. It is remarkable, therefore, that there should be such uncertainty concerning the effect of milk sterilisation in the case of infantile scurvy. One point is obvious. When data are collected clinically uncertainty as to the precise dietetic history of individual cases must always be considerable, and it is sure that even the occasional consumption of antiscorbutic substances in small amounts makes a great difference in the result. But we may perhaps find, as Funk suggests, a more important factor of uncertainty in the varying qualities of the milk-supply itself. There are a great number of circumstances which induce variations in the ordinary known constituents of milk, and Funk has produced evidence to show that the vitamine related to beri-beri may vary in amount. It occurs to one that such a special substance as an antiscorbutic might well tend to fail toward the end of a long lactation. Mixed milk-supplies must vary much in the proportion they contain of early lactation and late lactation products as well as varying in other ways. It is not at all impossible that one type of milk may, for one reason or another, withstand, in respect of its antiscorbutic power, more severe treatment than another.

I have dwelt a little upon this familiar subject for two reasons. First, because it illustrates certain difficulties inherent in the study of deficiency diseases; and secondly, because it seems to me that recently acquired facts suggest that, in spite of all that has been done, there is yet room for further investigations concerning the relation between milk sterilisation and infantile scurvy; investigations which must be made under conditions more carefully standardised than before. The same may be said with regard to rickets. Even those who are convinced that rickets takes origin from a dietetic deficiency have to admit that it is difficult to find a common factor among the dietaries held to be responsible for the condition. But now that we know how small in amount and how unstable in character certain essentials of food may be, our inquiries into the dietetic history of patients should become more detailed than before, and carried out perhaps with more faith in their bearings.

I should like to touch next upon pellagra, but time permits only the briefest reference. It once seemed probable that this disease might prove to be due to a diet deficiency quite different in nature from those we have hitherto considered. Maize is deficient in the aromatic amino-acid tryptophane, and a certain minimum supply of tryptophane is undoubtedly necessary to life. It would have been interesting to learn that a specific disease might arise from lack of an amino acid, and long ago, having shared in the discovery of tryptophane, I took a special interest in the etiology of pellagra, and performed a good many inconclusive, and therefore unpublished, feeding experiments. Dr. F. M. Sandwith has lately referred again to the possibility of this deficiency playing its part. But the recent demonstration, so largely due to Dr. L. W. Sambon, that pellagra occurs with some frequency in this country, and in individuals who have certainly not relied upon Indian corn as a basal diet, seems to put the suggestion out of court, as well as the view, much more widely held, that the disease is due to infected maize. If Dr. Sambon is right as to its probable frequency in this country the remark I made earlier with regard to the possibility of deficiency diseases sometimes occurring upon a normal diet can have no bearing here, and we shall have to admit that pellagra is not related to diet.

I propose to close with a brief reference to experiments of my own which relate to the effect of diet deficiencies upon growth. They have no very real relation to the present discussion, and I have already on more than one occasion made their results public. But I quote them now because they offer further conclusive proof that the removal of substances, minute in amount and of unknown nature, can produce an extraordinarily marked effect upon the physiological properties of a dietary. Upon a diet consisting of purified materials (one essential in the process of purification being thorough extraction with alcohol) young rats absolutely cease to grow, even when their consumption of food is quantitatively normal. On the other hand, if what is removed by alcohol be returned, or if very minute amounts of milk or fresh tissue extracts be added, the animals grow quite normally on the same basal dietary. I quote the results with special confidence now, because during a prolonged endeavour to discover the nature of the substances concerned, an endeavour which has continued until now, I have accumulated a great amount of experimental material. On the properly prepared diet not one rat out of many scores has ever continued to grow for more than a few days. Rats are so little prone to scurvy or to anything resembling the symptoms of beri-beri that they serve especially well to demonstrate this growth failure in a pure form.

Being in possession of a diet which, while supporting the animal for considerable periods, does not permit of growth, one was naturally tempted to try its effect upon the rate of development of cancer. Owing to the kindness of Dr. E. F. Bashford in supplying me with material I was first able some 18 months ago to make observations upon a strain of Jensen's rat sarcoma. All the rats to be used for the experiment were injected at the same time with a standard dose of tumour and fed for a few days upon a normal diet. They were then divided, without any selection, into two groups. One group was fed upon bread and milk, the other upon the purified artificial dietary. Otherwise the conditions were precisely the same. At a given period all the animals were simultaneously killed and their tumours dissected and weighed. Thirty-two rats upon bread and milk showed an average tumour weight of 14·5 grm.; 28 rats upon the artificial dietary gave an average weight of 3·9 grm. In the absence from diet of the substances which promote the growth of normal tissue the sarcoma grew at only one-fourth of its normal rate. Such a result has perhaps no more than an academic importance, but it shows that a neoplasm, like a normal tissue, requires for its growth certain at present unknown substances, which it acquires less readily from the tissues than from the food-supply of its host.

Cambridge.

SENSITISED VIRUS VACCINATION IN GONORRHŒA, AND ESPECIALLY ITS COMPLICATIONS.

BY LOUIS CRUVEILHIER, M.D.

THE method of sensitised virus vaccinations devised in 1902 by Professor Besredka[1] was first applied by me[2] to the treatment of gonorrhœa, and especially of its complications. We tried the method in several cases of prostatitis, and the complications of gonorrhœa which we systematically treated by this method were epididymitis, metro-salpingitis, and gonorrhœal rheumatism.

We thought it would be specially interesting to use Besredka's sensitised virus vaccination method for the treatment of *epididymitis*, which of all complications resulting from gonorrhœa is undoubtedly the most frequent. Most of the patients we have treated had been sent to us by our teacher, Dr. Castaigne, and our friends, Dr. Fouquet and Dr. Partnier. All our patients promised to use no other treatment; we advised them, however, to wear a well-made suspensory bandage.

In one case the pain was so acute as to cause the patient to faint, and in other cases the pain radiated towards the heart, the thigh, the loins, the gluteal region or the abdomen, yet it was very soon influenced by the treatment, so that most of our patients who complained of sleeplessness slept well on the very night following the injection. However acute the pain may have been in all the cases which came under our notice it usually disappeared within 12 hours after the first injection, sometimes after 24 hours, and we never observed it 48 hours after beginning the treatment, so that on the next day our patients experienced no more difficulty in standing or walking. In this way some of them were able to resume their work, and one of our patients, who delivered articles at houses, had to interrupt his work during 35 hours only.

The symptoms of local inflammation, such as redness, heat, and tension of the skin over the testicle, decreased and then disappeared together with the pain. In four cases after the second injection only, but more usually after the third—i.e., from five to eight days after commencing the treatment—we noticed the entire disappearance of tenderness on palpation of the epididymis. This organ recovered its normal sensitiveness as well as its usual suppleness and size. As a rule, however, we noticed the persistence of a painless nodule occupying the end of the epididymis. In one case a nodule was still perceptible three weeks, and in another case one month, after commencing the treatment.

In all our patients, none of whom was under the necessity of remaining in bed, all being able to come to our laboratory every morning to be examined or treated, we had the satisfaction of seeing that the various general symptoms usually accompanying epididymitis disappeared within a short time. As our patients were able to sleep and had ceased to suffer their appetite returned, and after two or three days' treatment they no longer presented the sickly, thin, and depressed aspect habitual
and epididymitis. The
inflammatory process
disappeared in the course of 24 hours after beginning treatment. Each of our patients had two or three injections administered at intervals of 48 hours. We have not a single relapse to report amongst the various cases which came to our notice.

We have tried the method of sensitised virus vaccination in the treatment of *utero-annexal complications* resulting from gonorrhœa, which so frequently necessitate serious surgical operations. In all the cases examined the results obtained were very good. Usually the very first injection brought about a considerable change for the better and lessened the discharge; after the second, and sometimes after the third, injection the abdomen recovered its suppleness and ceased to be painful on palpation, so that the p

could wear corsets again. The general health soon became excellent, and on examination of the uterus it was found entirely free from congestion, the annexa were supple, and there was only a slight glairy oozing in which it was not possible to discover the presence of the gonococcus. In cases of metro-salpingitis with effusion into the tube the satisfactory result of the method was not less evident, and a fortnight or three weeks after beginning the treatment the swelling noticed at the site of the tube disappeared, and usually only a very slight local sensibility was noticeable at the point of the insertion of the tube into the uterus. The method of sensitised virus vaccination appears to act even in cases of metro-salpingitis of long standing, and we obtained a complete cessation of all painful symptoms as well as of the discharge in the case of a woman whose infection dated from the time of her marriage nine years previously.

We thought it reasonable to try sensitised virus vaccination in *acute gonorrhœal rheumatism*. In cases of gonorrhœal rheumatism with acute pain which we had to treat the action of virus vaccination was very rapid; after four or five injections the patients usually desired to stop the treatment, as they no longer felt any pain or inconvenience on movement. In the case of patients who consented to return a fortnight or a month after the last injection in order to be examined by us we never found that any painful symptoms had reappeared.

In cases of gonorrhœal rheumatism taking the form of hydrarthrosis on the day following the first injection the patients expressed a manifest abatement of pain. After five or six injections a careful examination showed that the joint had become perfectly painless. The patient could bend his joint quite normally and execute every movement with perfect ease.

The form of acute arthritis is certainly the most common form of gonorrhœal rheumatism; now in every case we treated the results obtained were very good. This was specially so in the case of a patient who had been sent to us by Dr. Ravaut, and whom we treated with the assistance of Dr. Marato.

The patient last March became aware of a urethral discharge, as well as very painful symptoms of sciatica which soon obliged him to stay in bed. Notwithstanding the administration of aspirin,

attacked also.

On June 11th the first sensitised virus vaccination was done, and at the same time every other drug and local application were given up by the patient. Soon after the injection the pain in the spine had considerably abated. On the 13th a second injection was given, followed by a somewhat violent reaction, which, however, brought about a

In the opinion of all medical men *chronic gonorrhœal rheumatism* is particularly refractory to all treatment, so that it has been said that "its real treatment must above all be preventive, consisting in the treatment of gonococcic arthritis during its acute stage in order *to prevent it* becoming chronic." Now we thought *that the method* of sensitised virus vaccination might be of great use in this form of disease. It was found *so in the following* case.

The patient, who was sent to us by Professor Dopter, had for more than a year been suffering from pains in the joints of the right foot, knee, hip, and elbow, whilst on the left side the pain was in the heel, the knee and the wrist. The pain, which was acute and
on walking, had

[1] Besredka: Comptes Rendus de l'Académie des Science vol. cxxxiv., p. 1330.

[2] Louis Cruveilhier: Comptes Rendus de la Société de Jan. 4th, April 19th, June 28th, July 5th and 12th, 1913; Klinische Wochenschrift, August 11th, 1901.

On April 29th Professor Dopter asked us to apply our method and we gave [illegible] xt day the patient felt decidedly better. [illegible] on May 1st, 6th, 8th, 12th, and 14th. A [illegible] the painful symptoms, in the heel especially, was noted. The injections were repeated on the 16th, 21st, and 24th. Though not entirely cured the patient was considerably better, and on June 2nd the pain was no longer perceptible except in two toes of the right foot. The lameness is better and walking is becoming more and more easy, so that a complete recovery can be expected after a few more injections.

Finally, we have had quite recently the opportunity of treating four patients who had suffered for four, five, nine, and ten years respectively from pains in the joints which seemed to be refractory to all the medicines, such as salicylate and aspirin, usually employed against rheumatism. As these patients had formerly suffered from gonorrhœa, we thought it advisable to try the method of sensitised virus vaccination, and after two, three, and four injections we had the satisfaction of noticing either a considerable change for the better or an entire disappearance of the articular pains.

Experiences of this kind have led us to think that a large number of arthritic diseases, attributed to rheumatism, belong to the domain of gonococcic infection, and that in all cases of rheumatism where the usual treatment does not give any results, and especially when a gonococcic origin can be surmised or traced, it is well to have recourse to sensitised antigonococcic virus vaccination.

The action of Besredka's sensitised virus vaccination has been more especially observed by us in the course of complications resulting from gonorrhœal infection, but it is nevertheless true that we have obtained very good results in the treatment of *acute* and even *chronic urethritis*.

In cases of acute urethritis where our help was sought we always obtained most encouraging results. The pains and local inflammation disappeared in most cases after the second injection, and at the same time the discharge grew less abundant, and also very rapidly lost its yellowish-green colour and its thickness, and took the aspect and fluidity of soapy water. The time of its disappearance was different in various cases, but after an interval of four weeks its disappearance was usually complete. None of the cases we treated showed any complication whatever.

Chronic urethritis appeared to us to be as beneficially influenced by our method of sensitised virus vaccination as the acute form of this disease. From the very first injection we always noticed a rapid decrease of secretion as well as a notable change in its appearance, for it soon became transparent like glycerine. All other disorders imputable to former prostatic infections, such as a feeling of heaviness near the anus, perineal pains, as well as pain in the region of the sacrum, usually disappeared after the first injection.

Remarks.—We have not yet come to any final conclusions concerning the various modifications which, in our opinion, ought to be made in Besredka's method of sensitised virus vaccination in order to adapt it to the treatment of gonorrhœa. Yet we are able to state that, as has been proved by the experiments of Metchnikoff and Besredka[3] in antityphoid vaccination, it is always preferable to inject living sensitised virus. In a certain number of cases, when we had absolutely failed whilst persisting in using dead sensitised virus, we obtained excellent results from the use of living sensitised virus The serum which we employed in our operations was taken from a she-goat to which we had successfully applied Besredka's subintrant injections of the veins in order to render it immune.[4] We considered that it was not advisable to take from the patient himself the gonococci to be sensitised, and we took them from the cultures which we had had in stock for several months, and several samples of which were obtained by the kindness of Messrs. Maras and Forgeaud. Our injections were principally made in the subcutaneous cellular tissue and were repeated at intervals varying according to the different cases. None of the patients who had recourse to our help showed any sign of severe general reaction. In some cases there was a slight rise of temperature during the hours which followed the injection. Sometimes we also noticed at the site of the injection some erythema accompanied by a pain which never lasted longer than 48 hours.

SOME ADDITIONAL EXPERIENCES OF NERVE SURGERY.

BY A. H. TUBBY, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE WESTMINSTER AND THE ROYAL NATIONAL ORTHOPÆDIC HOSPITALS, ETC.

A CONTRIBUTION on "Nerve Surgery" was made by me to the Sixteenth International Medical Congress, held in Budapest, and was published in THE LANCET of Sept. 4th, 1909, p. 706. An opportunity is now taken of tracing the further progress of the cases then referred to, and of adding new ones.

The operation for facial paralysis by facio-hypoglossal anastomosis has proved to be a permanent and almost complete success. The patient was shown at the Royal Society of Medicine in 1909, and it was then difficult to distinguish which side of the face had been affected, except for the fact that there was, in repose, a very slight droop of the left angle of the mouth. All the movements on that side of the face were perfect, there was a total absence of associated movements of the tongue and face, and the tongue was protruded directly and without any deviation.

Of the cases of operation on the brachial plexus[1] one was for Erb's or the upper arm type of infantile paralysis, where the anterior branch of the fifth cervical nerve was grafted into the sixth, with gradual recovery of power in the biceps and partial recovery in the deltoid,[2] the fibres to these muscles on the outer and upper part of the fifth nerve cord being split off and inserted into the sixth nerve cord. Improvement took place in the deltoid in so far that three years after the operation the arm could be abducted 8 inches from the side, when the scapula was held. A better result would have been obtained if the significance of a paralytic subluxation of the shoulder had been recognised and the looseness of the capsule rectified as a preliminary step.

A case of severe laceration of the brachial plexus and complete paralysis of the right arm was also reported upon.[3] Here there was absolute and complete paralysis of the whole of the muscular and sensory area supplied by the brachial plexus. All the nerve roots were found to have been torn apart, and were matted together by fibrous tissue; scar tissue also intervened between the proximal and distal segments of the nerves. The scar tissue was excised and the proximal and distal segments of the plexus were sutured together *en masse*. Five years afterwards—that is, in March, 1911—the recovery of motor power had extended to the biceps, brachialis anticus, and the deltoid. The patient could flex the forearm fully and abduct the upper arm to a right angle, sensation had returned over the distribution of the upper external cutaneous branch of the musculo-spiral nerve and over the internal cutaneous branch of that nerve, and recovery is still slowly progressing.

Neuroplasty on the popliteal nerves, after anterior poliomyelitis, has not been by any means so successful, and an explanation may be found in Warrington and Murray's hypothesis[4]—viz., that, "there may be sufficient nerve cells left to supply one group of muscles, but insufficient to supply two"; or, to put it in another way, there are enough cells to supply the internal popliteal nerve, but not the external as well, and *vice versâ*. In one case where the distal part of the external popliteal nerve was grafted into the internal no result followed, perhaps due to the fact that there was also some degeneration in the internal trunk, or that the remaining nerve cells were insufficient.[5]

In a second case, one of paralytic equino-varus, where the distal part of the external popliteal was grafted into the internal popliteal nerve, no sign of recovery was observed during two years, and then the area of the previous operation was exposed. It was then found that the grafted portion of the external popliteal nerve was evidently undergoing regeneration, as shown by the increasing size of its distal part as compared with the free proximal part, and by its whiteness, roundness, and firmness. It was further noted that direct stimulation of the distal or grafted portion of

he external popliteal nerve caused contraction of the anterior nd external leg muscles. Here the outlook may be described s distinctly hopeful.

One example of talipes calcaneus, where the nerves to the oleus and gastrocnemius were separated from the internal opliteal trunk and grafted into the external, showed partial ecovery during a term of three years, but the condition has been stationary for the next three years; that is, whilst the patient has recovered sufficient voluntary power to plantar-flex the foot when it is off the ground, yet when seen in July, 1913, the *improvement in muscular strength* had been rrested. And a similar remark may be made of another case of talipes calcaneus where the range of ankle movements became almost normal, without, however, there being sufficient strength to lift the weight of the body on the toes of the affected foot alone. Such is the record up to date of cases of nerve-anastomosis and neuroplasty reported previously.

We must now pass on to more recent cases.

CASE 1. *Traumatic lesion of the brachial plexus; operation; nearly complete recovery.*—A male was admitted to Westminster Hospital on Sept. 9th, 1909, with a history that 12 months ago he had been knocked

Deductions.

1. Brachial plexus lesions, if traumatic, are hopeful, if the loss of power has not existed for years. If due to other causes the outlook is not so good. However, we should not despair of a case recovering, even five years after the operation, provided that the improvement has set in within three months after the operation and is continuous.

2. [illegible] ntile paralysis has proved [illegible] previously.

3. Injuries about the wrist should never be sewn up until the continuity of the nerves has been ascertained, and until all the electrical reactions have been tested.

4. If the lesion of the nerve is compression by a scar the outlook after operation is most hopeful. [illegible] the nerve has

been severed primary operation is very hopeful, but secondary suture rarely permits a complete recovery.

5. No case, however, of traumatic nerve lesion should be regarded as hopeless, in view of the achievements of neuroplasty.

Finally, I should like to make a note on a painful condition connected with enlargement of the head of the first metatarsal bone, and I beg to refer to those cases where there is not only tenderness on the inner side of the joint, but also severe pain on its outer side and in the first interdigital space. This is a condition special to those cases where there is lipping of the joint surfaces and a deposit of osteophytes, and the cause appears to me to be as follows: On dissecting the part there will frequently be found a communicating branch passing from the digital trunk of the anterior tibial nerve to the corresponding nerve on the plantar surface. This communicating branch arises opposite the most prominent part of the head of the bone and passes immediately downwards over the capsule of the joint, to which in inflammatory cases it is often adherent, and it joins the digital branch of the internal plantar to the outer side of the great toe. It is easy to see how painful compression may arise, and the remedy I have adopted is simple—i.e., to dissect away the communicating branch and remove the osteophytes.

Harley-street, W.

PUBLIC MEASURES FOR THE PREVENTION OF TUBERCULOSIS.[1]

BY NATHAN RAW, M.D. DURH., F.R.C.S. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO MILL-ROAD INFIRMARY, LIVERPOOL; MEMBER OF THE INTERNATIONAL COMMITTEE ON TUBERCULOSIS.

THE spread of tuberculosis in any community can only be efficiently and successfully checked by the adoption of public measures which will form a coördinated scheme for attack on the disease. Tuberculosis being to a large extent a disease of ignorance and misery, our efforts to prevent it must be directed towards the social conditions and insanitary surroundings of the poor. It is essential that a very close coöperation must be established between voluntary action and Government and municipal efforts in order that the spread of the disease can be controlled and proper means provided for the treatment and cure of those afflicted.

The general measures for the control of tuberculosis will be somewhat as follows: (1) Voluntary and compulsory notification; (2) removal of affected children from school and home; (3) treatment of children in special children's sanatoriums; (4) education of the general public with regard to the disease; (5) provision of municipal dispensaries in every community; (6) provision of sanatoriums for the cure of early cases; (7) institutions for advanced cases; (8) home training and supervision amongst the working classes; (9) rigorous supervision of the milk supply; (10) extermination of tuberculosis amongst cattle; (11) assistance to family in the absence of the breadwinner; and (12) provision of suitable employment to cured cases and those in whom the disease is arrested.

Voluntary and compulsory notification.—Tuberculosis being essentially an infectious disease it is desirable that a complete notification of all cases should be made to the officials who are responsible for the public health, so that they may be informed as accurately as possible of the existence of every person infected with the disease.

In England voluntary notification has been superseded by compulsory notification, at least so far as pulmonary tuberculosis is concerned, and although it is open to question whether or not it is desirable to notify the private patients of a medical man, yet if a certain amount of discretion is exercised there can be no doubt but that compulsory notification is in the general interest of the community, although it may press hardly on individual cases. A recent order from the Local Government Board, in London, compels the notification of every inmate of a public institution suffering from any form of tuberculosis. This notification must be made on special forms by the physician attending the case, and for which he receives a small fee of 1*s.* As soon as notification is received by the health officer a visit is made to the home of the patient, and a careful inquiry as to his personal condition and surroundings is made; if, in the opinion of the health officer, his home surroundings are such as to make it unsafe for him to remain power is given for the patient to be removed to some institution, but this power is very rarely exercised.

In large cities and habitations where a great amount of overcrowding exists, the treatment of the advanced case of tuberculosis is of supreme importance. If he is allowed to live in the same dwelling and share the same room as his wife and children, it will almost certainly happen that one or all of his family will become infected with the disease, and therefore it is absolutely necessary that he should be removed to some safer surroundings unless he is able to have a room to himself and to look after his own personal cleanliness. It is of no use to keep a patient in a sanatorium for six months and then discharge him as incurable, to spend the rest of his life in an overcrowded cottage where he may spread the infection to a new generation. Provision ought to be made, either by Govenment or by municipality, for the detention and comfortable treatment of all cases of incurable tuberculosis. I am not in favour of exercising compulsory powers of removal from a man's own home, but if it is for the protection of healthy people, then removal ought to be made compulsory; but I think it will be some time before public opinion is ripe for such measures.

The health authority will disinfect and clean the clothing and bedding of any notified case, and then will also carefully disinfect the house in which he has lived. Very often the patients complain of this attention to their homes and their clothing, but it is essential that it should be done for the protection of the future residents of the house. It is also the practice to notify to the health authorities any change of address of a tuberculous person, so that they may keep in touch with any house in which he may live.

On the whole, compulsory notification will prove useful in the fight against the disease, but it should only be used in a wise and gentle manner, as otherwise it is liable to cause personal discomfort and may have the effect of ostracising the patient from society. If it is pushed too far it may also have the effect of preventing him from earning his livelihood by reason of his fellow-workers having a fear of infection in the workshop or factory. Although many countries are still doubtful as to the wisdom of enforcing compulsory notification, yet from the point of view of suppression of an infectious disease it cannot be denied that with care and consideration the compulsory notification of tuberculosis is bound to do good.

Removal of affected children from school and home.—The medical inspection of school children is now thorough and complete in Great Britain, as in many other countries, with the result that a fair number of children of school age are recognised as suffering from pulmonary tuberculosis, although this number is not so large as one might be inclined to expect. Pulmonary tuberculosis is comparatively uncommon amongst school children, whilst the other forms of tuberculosis are more often seen. When a child is recognised as suffering from open tuberculosis it should at once be removed from school, mainly for the protection of the other children, as it is possible for one child in an overcrowded and badly ventilated schoolroom to infect several of its fellows. In the case of a family the infected child should invariably, if possible, be provided with separate accommodation, or, better still, removed from the family circle until recovery has taken place, but on no account should the child sleep with any other children or even with its parents.

Treatment of children in special children's sanatoriums.—The provision of special sanatoriums for children is, I am glad to say, in England making steady and rapid progress; many of these sanatoriums have been provided by the education authorities, with excellent results. It has been found undesirable for children to be treated in a sanatorium for adults; hence it is necessary to provide special institutions for them. The children's sanatorium has the double advantage of continuing the education of the child and at the same time providing the means of cure of the disease. In Germany, where the climate is more suitable for this treatment, a great many of such sanatoriums have been provided, and in Great Britain much success has attended their adoption.

---

[1] Being a report presented at the Eleventh International Anti-Tuberculosis Conference, Berlin, Oct. 22nd to 25th, 1913.

Education of the general public with regard to the disease.—The main point in the campaign against tuberculosis must be in the education of the general public with regard to the disease. The National Association for the Prevention of Consumption aims almost entirely at this part of the work; it has numerous branches in most of the large cities and towns of the British Isles, where the work of education of the public is steadily pressed forward. A travelling exhibition, provided with models of everything necessary in the treatment of the disease, is constantly moving round from place to place, and demonstrations are given by competent teachers on the management and nursing of children, and the prevention of tuberculosis, in which popular lectures are given each evening by experts. In this way an enormous amount of information is steadily disseminated. Education of school children is constantly going on, and the teachers themselves are instructed in the methods of prevention and treatment of tuberculosis. Literature is scattered broadcast throughout the land, and illustrated posters are affixed in every town, so that every possible means is used to convey to the public the information so much required.

Provision of municipal dispensaries in every community.—The public dispensary has been proved to be of value in the treatment of poor persons afflicted with tuberculosis, and it is suggested that in every town the health authority should provide the municipal dispensaries where the poor may receive attention, and where the most careful inquiry can be made with regard to their families. The house of every infected person is carefully inspected and the accommodation noted. Advice as to nursing, isolation, and treatment is given in every case, and where necessary rigorous action is taken by the health inspectors. In this way it is hoped that every affected person may have the opportunity of receiving advice and treatment, together with assistance to his family if necessary. The National Insurance Act in England will quite revolutionise our present methods in dealing with tuberculosis. Every insured person is entitled to special treatment and if necessary to sanatorium benefit. In the case of anyone transferred to a sanatorium the dependents of the family will receive 10*s.* per week for six months, and if necessary further assistance will be given to the affected person. This is a great step in advance, and will undoubtedly induce a great many of the working class to accept treatment in a sanatorium, knowing that their family will be provided for in the meantime.

Provision of sanatoriums for the cure of early cases.—The provision of sanatoriums for treatment and cure is of vital necessity. Tuberculosis in its early stages responds admirably to sanatorium treatment, and it must be our aim in the future to obtain the cases at the earliest possible moment, so that they receive special treatment with a view to cure, and also receive special education and instruction with regard to their manner of living in the future. The sanatorium itself should be reserved for early cases of tuberculosis—it cannot be expected to do much good in advanced cases and being of a very costly character its resources should be reserved for hopeful and curative patients. In the national insurance scheme such sanatoriums will be erected in every locality, and every suitable case will have the opportunity of cure. The results of sanatorium treatment have been excellent, and it is hoped that they will be still further improved as a better selection of patients is made.

Institutions for advanced cases—In my opinion the most potent factor in the spread of tuberculosis is the advanced case who is not under proper supervision. The man in the final stages of consumption, who is pouring out millions of bacilli from his lungs each day and who has not physical strength to look after himself or take ordinary care, is a serious danger to the community These are the people who require the most rigorous supervision and who as a rule are neglected by everybody. The late Professor Koch often said that he attributed the steady decrease in tuberculosis in England to the fact that such a large number of advanced cases of tuberculosis were isolated and treated in the Poor-law institutions of Great Britain; this statement is undoubtedly true, and the very fact that so many were constantly segregated must have had a great influence in the decline of consumption. Special institutions should be provided for advanced cases where they may be made comfortable and happy to the end, but it is doubtful if it would be wise at present to enforce isolation of such cases, although I have no doubt that in the future this will have to be done.

Home training and supervision amongst the working classes.—Tuberculosis being a disease of long standing it is necessary that those who suffer from it must be instructed in the manner of living at home. It is essential that the working man or working woman must attend to his daily duties, in many cases for years, whilst he is suffering from it; hence if he is to live at home with safety he must know how to protect the other members of his family. There is a strong prejudice in England against the working man using a sputum flask in the workshop or factory, so that there is every temptation for him to conceal the disease. It is not desirable, however, that a workman should be treated as a leper because he happens to be infected with tuberculosis, otherwise he is in danger of losing his ordinary place in the labour world and becoming a burden on the community. It is much more necessary that he should be instructed how to take care of his expectoration, and how to prevent the slightest tendency of infection to the healthy members of the community; and if this is done there is no reason whatever why he should not attend to his daily work and associate himself in ordinary social life There is a great danger of frightening co [illegible] fee [illegible] pu [illegible] munity, and of urgent importance as the staple food of infants and children. Notwithstanding what has been said by many experts in different countries there is no doubt whatever but that a large amount of tuberculosis is conveyed to children by means of infected milk and food. Tuberculosis is very common amongst dairy cows in Great Britain and Ireland—in fact, about 20 per cent. of cattle are infected with the disease at the present time. It is shown, however, that the cows with tuberculosis of the udder are by far the most dangerous, hence only about 2 per cent. of the infected cows are highly dangerous to children. It is the practice, however, in this country to mix all the milk from a herd of cows, so that one cow with disease of the udder may contaminate the whole milk-supply. Whilst consumption is steadily decreasing in this country the same cannot be said for tuberculosis in children. A very large number of the lesions occurring in children are the result of infection from tuberculous animals in the form of food, and every possible step must be taken to prevent such contamination of the food-supply.

Legislation has recently been introduced in England with a view of establishing a pure milk-supply, and it is proposed that all persons offering milk for sale should be registered and their premises periodically inspected. Every cow supplying milk will be under rigorous inspection by the health authorities, and compensation will be paid to the owner of any cow which is found to be suffering from tuberculosis. In the meantime the public are advised to sterilise the milk before being given to infants, with a view to destroying tubercle bacilli and other organisms. In Liverpool a great amount of special care has been taken by the health authority in safeguarding the milk-supply. Special powers have been obtained to inspect the source of all milk coming into the city, and the result has been that I have myself observed a steady decrease in hospital of children suffering from tuberculosis.

The amount of disease which is conveyed from animals to man seems to vary in different countries. In Scotland there is more than in England, whilst in the British Isles there appears to be more tuberculosis conveyed by milk than on the Continent, where it is almost the universal practice to pasteurise the milk before drinking. Whether this be so or not, we are all agreed that in the campaign against tuberculosis every effort must be made to eradicate the disease from dairy cows. This, I admit, is a very costly undertaking, and millions of pounds would be required to do it effectively in England alone. The scheme suggested by Bang, in Copenhagen, has had excellent results, and a similar process should be gradually introduced into every country.

Assistance to family in the absence of the bread-winner.—The question of providing assistance to the family in the absence of the bread-winner during his stay in sanatorium has been to a great extent solved by the provision in the National Insurance Act already referred to, but this work requires further extension, and a central fund ought to be provided in every community for the special purpose of looking after the family when the parent is undergoing cure, otherwise it is impossible to expect him to give himself up for treatment for any prolonged time.

Provision of suitable employment in cured cases, and those in whom the disease is arrested.—The question of providing suitable employment for cured cases, and for those in whom disease is arrested, is one of great difficulty, although of immense importance. A very great many private employers are now giving such workers out-of-door, easy employment, as it is only in this way that they can be expected to remain well and fight the battle of life. We wish to extend such a practice in every country, and appeal confidently to those employers of labour who have the opportunity of making such provision for their workers.

By adopting a combination of measures such as those enumerated upon, we can confidently hope slowly but surely to exterminate the disease which ought not to be in our midst, but which is provoking such an amount of havoc, misery, and loss of human life.

Liverpool.

THE BACTERIOLOGICAL DIAGNOSIS OF A CASE OF PLAGUE.

BY W. J. TULLOCH, M.B., CH.B. ST. AND.

(From the Bacteriological Laboratory, College of Medicine, Newcastle-on-Tyne.)

THE following case is of interest in that it illustrates some of the many difficulties that exist in recognising cases of plague when they arrive at uninfected ports.

A boy 16 years of age, an apprentice on a grain ship that arrived in the Tyne from Rosario (River Plate), was taken ill on Sept. 10th, 1912. He was seen on the following day by Dr. W. E Harker, medical officer of the Tyne port sanitary authority, who found him suffering from an indefinite febrile condition with high temperature, and it was noticed that he had a slightly enlarged and painful gland at the angle of the left jaw. In view of the fact that another apprentice had died at a continental port a few days previously from a condition which, as a result of post-mortem examination, was diagnosed as enteric fever, it was thought very likely that this boy had the same disease. The gland steadily subsided, but on the third day of illness signs of basal pneumonia appeared, and three days later the boy died, the cause of death at the time being uncertain.

At the post-mortem examination, made two days after the death of the patient, no gross pathological changes were noted beyond basal consolidation of the lungs, slight pleuritis, and some enlargement of the spleen.

Bacteriological examination.—At the first clinical examination material was taken for bacteriological investigation by puncturing the enlarged gland, and blood was obtained for carrying out an agglutination test with B. typhosus (Sept. 11th) The agglutination test was made at once, and it was found that the serum agglutinated B. typhosus in a dilution of 1/100 in one hour at 37° C. (The bacillus employed agglutinates with most typhoid sera in dilution of 1/100, while a certain number of sera agglutinate it in 1/500 dilution.) The material obtained from the gland—about 0·5 c.c. of fluid—was spread over the surface of three small agar tubes. After 48 hours' incubation at 37° C. four small colonies appeared. These consisted of organisms having the morphological and staining characteristics of B. pestis. Microscopical examination of the fluid had failed to show the presence of organisms.

The above findings indicated a further examination of the case by means of blood culture for the following reasons: (1) That the serum of the patient agglutinated B. typhosus fairly actively; (2) that the apprentice who had died at the continental port and who was said to have succumbed to enteric fever had only been ill five days; and (3) "a severe septicæmia may be present at a comparatively early stage of the disease"—plague (Indian Plague Commission).[1] It was important then in the present case to examine the blood by cultural methods—firstly, to exclude enteric fever, and secondly, in the event of the case being one of pneumonic or septicæmic plague, positive evidence of the nature of the infection would be rapidly and certainly obtained. Fifteen c.c. of blood were obtained by venipuncture of the median cephalic and run directly into 100 c.c. of broth. After 48 hours' incubation at 37° C. a few chains of Gram-negative polar-staining cocco-bacilli were noted in films made from the blood culture. By subculture on agar a plague-like growth was obtained.

The bacteriological examination of the organisms obtained from the gland and from the blood presented no difficulty. The growth on agar and other media and the biochemical reactions were typical of B. pestis, as also were the results of animal inoculation.

Three guinea-pigs were inoculated (rats could not be obtained at the moment). (*a*) One animal was inoculated in the flank subcutaneously with 3 c.mm. of an emulsion of a 24 hours agar culture suspended in 3 c.c. of saline. The animal died on the sixth day, and on post-mortem examination lesions typical of plague were noted—a mass of hæmorrhagic and necrotic tissue at the site of inoculation, injection and enlargement of the glands, and marked enlargement of the spleen, which was filled with hæmorrhagic and necrotic nodules. (*b*) A second animal inoculated with a similar quantity of the 48-hour blood culture died after two days, the examination revealing evidence of septicæmic infection—small hæmorrhages, particularly on the serous surfaces. (*c*) The third was inoculated by Bannerman's cutaneous method. The result was similar to (*a*) above.

A diagnosis of plague was made on the following grounds: (1) the microscopical and cultural characters of the bacillus obtained from the human material and from the lesions produced in the guinea-pigs; (2) the biochemical reactions of the organisms from both sources; (3) the control of the organisms recovered from the animals by culture on bile-salt media; and (4) cultural and histological examination of the lungs, liver, and spleen of the patient revealed the presence of B. pestis in these organs. In the lungs the organism could not be demonstrated in the alveoli, being found only in the capillaries, while the air spaces were filled with a polymorphonuclear exudate containing Gram-positive streptococci. The pneumonia was then apparently secondary and the case one of septicæmic, not of pneumonic, plague, and it seems probable that the gland condition was an early and slight involvement of the lymphatic system preceding septicæmic plague.

Criticism.—The result of the examination by blood culture shows, I think, that this method is one of which a more extensive use might with advantage be made, and one might go so far as to suggest that it would be well if it were employed in every case of febrile disturbance of indefinite nature occurring on ships coming from abroad. Especially is there danger of a wrong opinion being given on clinical grounds in cases of "pneumonia." "Pneumonia" occurring on ships arriving from ports where plague, epidemic or epizootic, is known to exist is potentially pneumonic plague, and before a diagnosis of pneumococcal pneumonia is made the former should certainly be excluded by bacteriological methods. Let us assume that this boy had been the first case of the disease to occur on board the ship, and let us suppose that he had been taken ill two or three days before the vessel arrived in the Tyne. The gland condition would have subsided, and a (clinical) diagnosis of pneumonia would have been justified by the symptoms and physical signs of the case. Again, considering the agglutination of B. typhosus by the serum of the patient along with the physical signs one might well have expressed the opinion that the case was one of ambulant enteric fever complicated by pneumonia. In such circumstances the true nature of the infection would not have been appreciated and the disease might have been widely disseminated. I state this hypothetical case to emphasise the importance of the information obtained from blood culture in making the diagnosis of indefinite febrile maladies occurring on board ship. As blood culture is a certain method of diagnosis in the septicæmic form of plague, and is a valuable aid to the diagnosis of other forms of the disease, this procedure should in my opinion be made a routine practice in the examination of such cases. Not only does it give definite information in a large number of cases of infection with B. pestis, but it will frequently serve to exclude infections with other organisms.

Newcastle-on-Tyne.

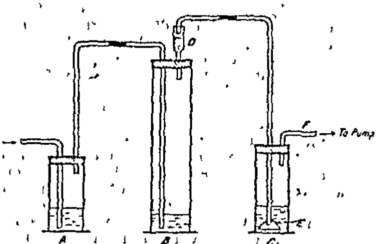
THE ESTIMATION AND SIGNIFICANCE OF AMINO-ACIDS IN THE URINE IN DIABETES MELLITUS.

BY P. J. CAMMIDGE, M.D. LOND.

IN 1894 Mies[1] reported the case of a little girl suffering from diabetes in whose urine an abundant deposit of tyrosine crystals occurred. Since that date Nicola,[2] Abderhalden,[3] Mohr,[4] and others have described cases of glycosuria in which as much as 0 4 grm. per litre of that substance has been excreted in the urine. Bergell and Blumenthal[5] also found that tyrosine occurs in the urine of depancreatised dogs. Very little attention appears to have been devoted to other amino-acids, however, or to the total output in various types and grades of glycosuria. This is due, no doubt, largely to the lengthy and laborious processes generally employed for their separation and estimation. During the last few years I have met with several cases of diabetes in which tyrosine crystals appeared in the urine when unfavourable clinical symptoms leading to a fatal issue set in, and it occurred to me that if one could easily obtain even a rough estimation of the amino-acid excretion it would be [illegible] ment [illegible] the direct estimation of the [illegible] ave led to the degree of acidosis being more generally determined indirectly by the amount of ammonia nitrogen passed. For this purpose two methods are commonly employed, Folin's[6] and Malfatti's.[7] In the former the ammonia present in a measured quantity of the urine is aspirated through a known quantity of standard sulphuric acid, and the amount of acid neutralised ascertained by titrating with a standard solution of caustic soda. For this purpose the apparatus shown in the figure is used.



Sketch of apparatus used in the Folin method of estimating ammonia in urine.

A is a wash-bottle containing strong sulphuric acid to remove ammonia from the aspirated air. Into B are placed 25 c.c. of the urine, a few c.c. of paraffin oil (to prevent frothing), and about 1 grm. of anhydrous sodium carbonate. This is at once connected up to C, which contains 25 c.c. of decinormal sulphuric acid, diluted with 25 c.c. of ammonia-free distilled water, and a few drops of a solution of alizarin red. D is loosely packed with wool to prevent any sodium carbonate being carried over, and the other end of the delivery tube is provided with a Folin's absorption apparatus (E) to bring the aspirated air into intimate contact with the acid in C. When the connexions have been made, F is joined up to a filter-pump attached to the water-supply and air drawn through for two hours. At the end of that time the apparatus is disconnected, and E is washed with ammonia-free distilled water into C, the contents of which are then titrated with decinormal sodium hydroxide sol[illegible] the quantity [illegible] amount of ac[illegible] of urine. To express this as ammonia nitrogen it is multiplied by 0·0014 grm., and from that the percentage and the total ammonia nitrogen in the output of urine for the day can be calculated.

The Malfatti process depends upon the fact that ammonia salts react with formaldehyde in neutral solution to form hexamethylenetetramine, setting free the acids with which the ammonia was combined. These can then be titrated with an alkali. 10 c.c. of the urine are diluted with about 50 c.c. of ammonia-free distilled water and three or four drops of a 1 per cent. alcoholic solution of phenolphthalein added. Decinormal sodium hydroxide solution is run in from a burette and the reading taken when a permanent faint pink colour develops. 3 c.c. of a neutral solution of formaldehyde (prepared by diluting commercial formalin with an equal volume of distilled water, and adding just sufficient decinormal sodium hydroxide to neutralise the mixture, using phenolphthalein as the indicator) are then added, when it will be found that the pink colour disappears. A further addition of decinormal sodium hydroxide is now made until the pink colour is just restored, and the reading is again taken. The difference between the first and second readings is multiplied by 0·0014 grm. and the result by ten to obtain the percentage of "ammonia" nitrogen. From this the content of the 24 hours urine is readily calculated. The addition of neutral potassium oxalate has been shown by Mathison[8] to give a sharper end-point when phenolphthalein is used as the indicator.

Amino-acids react like ammonia to formaldehyde, so that the result obtained by the Malfatti process is the sum of the ammonia and the amino-acids present in the urine, but with Folin's method the ammonia only is estimated. If, therefore, a urine is examined by the two processes the difference between the results will be a measure of the amino-acids present. I have been employing this method of estimating the amino-acid nitrogen for some time and obtained results which have proved of great service in treating diabetes and giving an opinion as to the probable course of my cases.

The amino-acids are comparatively simple chemical bodies of known molecular structure, consisting of an acid, of more or less complex composition, in which an NH_2 group is substituted for one of the hydrogen atoms attached to the carbon atom nearest to the acid radicle. Unlike the proteins, albumoses, and peptones, the amino-acids can be obtained in a pure crystalline form, and constitute the "Bausteine," or building stones, of which the proteins are composed. The varieties and proportions of the amino-acids in different proteins vary considerably, and this, as we shall see later, is a matter of considerable importance in the treatment of diabetes. It has been proved conclusively that the proteins of the food are broken down by the digestive processes into the individual amino-acids of which they are composed, and that it is these, and not, as was at one time supposed, the albumoses and peptones which are absorbed by the walls of the intestine. Their subsequent fate is to a certain extent a matter of speculation, but they undoubtedly constitute the material from which the tissues obtain their supply of nitrogen, and they also contribute to the production of energy. Some observers have maintained that the amino-acids are resynthesised to blood proteins during their passage through the intestinal wall. Others have held that they are partly de-nitrogenised in the course of their absorption, and that the process is carried still further in the liver, the liberated ammonia being converted into urea by the hepatic cells and the non-nitrogenous portion used as a source of energy. A third, and more recent, view is that the amino-acids products of digestion pass into the circulation as such, and are transported to the tissues in the blood-stream; those that are needed for repair of the tissues are then utilised for that purpose, while the unsuitable and unneeded amino-acids are broken down, the nitrogen being converted into urea and the non-nitrogenous portion transformed into dextrose in some instances and in others directly oxidised into carbon dioxide and water like the simple fatty acid constituents of fat, furnishing in either case a source of energy for the organism. Since amino-acids have been most frequently met with in conditions in which there has been serious disease of the liver, such as phosphorus poisoning and

---

[illegible]

[8] Brit. Med. Jour., 1909.

acute yellow atrophy, it has been assumed that the splitting off of nitrogen and formation of urea from the amino-acids not needed for repair purposes by the tissues takes place in the liver, but Folin and his fellow-workers[9] consider that the process is not confined to any particular organ and may be carried out by various tissues, very probably to a preponderating extent by the muscles. In addition to severe hepatic diseases, diabetes, and after extirpation of the pancreas in animals, amino-acids have been met with in the urine in typhoid fever, small-pox, erysipelas, pneumonia, leukæmia, gout, during pregnancy, and in children with gastro-intestinal disorders. In some of these conditions at least the amino-acids found in the urine are not primarily of alimentary origin, but arise from the breaking down of the tissue proteins, and they are excreted in the urine because the quantity formed is too large for the body to deal with in the ordinary way by de-aminisation and oxidation, &c., or the tissues have more or less completely lost their power of splitting some of the amino-acids formed.

The conception of glycosuria as a symptom of a disturbance of metabolism which, although varying in severity, is essentially the same whatever the primary cause may be, is now very generally accepted and has done much to improve our methods of treatment. It is important, however, that we should distinguish two, or possibly three, stages if satisfactory results are to be obtained. In two of the three the defect in metabolism is confined to a more or less complete inability to make use of the sugar derived from carbohydrate foods, but amino-acids are still available as a source of energy, and the body makes use of these, supplemented in the milder forms by a certain amount of sugar derived from starchy foods, and fats for its needs. In the third form, to which the name "diabetes" is confined by some writers, the power to metabolise amino-acids is diminished, with the result that these bodies appear in the urine and gradually increase in amount as the metabolic defect becomes more pronounced. Even in the most serious cases, however, some of the amino-acids are de-aminised and carried as far as dextrose, thus contributing to the sugar excreted in the urine, while the fatty acids of others are imperfectly oxidised and give rise to the acetone bodies (acetone, aceto-acetic acid, and oxybutyric acid) that are passed at the same time. Estimations of the amino-acids, acetone bodies, and sugar give therefore a much more complete picture of the state of the metabolism than any one of these taken alone, and by considering them in conjunction with the effects produced by a diet of which the qualitative and quantitative composition is known we can determine the stage that has been reached and the probable expectation of life.

In this communication I shall confine my remarks to the amino-acids, and only deal with them from the aspect of their determination by the method referred to. The varieties and quantities of the different kinds met with in various types of glycosuria and at successive stages of the condition are matters that are under investigation at the present time. I have found that the urine in simple cases of glycosuria shows no amino-acid nitrogen by the method described, excepting when there is evidence of a gouty condition or serious hepatic derangement; there may then be as much as 0·5 grm. in 24 hours. In such cases the urine may contain traces of acetone, but it is free from aceto-acetic and oxybutyric acids. When secondary disturbances of metabolism occur and the patient has reached the third stage, the amino-acid nitrogen is small in amount at first, 0·05 grm. or less, but as the disease progresses, and especially if it is not controlled by suitable treatment, it generally increases rapidly, often much more rapidly than the acetone bodies, until 2·0 grm. or more are being excreted daily. Finally, the amino acids may be present in such abundance that the relatively insoluble tyrosine crystallises out and can be recognised in the urinary sediment with the microscope. In some cases the excretion of amino-acids and acetone bodies run parallel, but this, as I have just pointed out, is not always the case, and one sometimes meets with a high excretion of acetone bodies and a low amino-acid nitrogen, while other cases show the reverse condition. The former often do surprisingly well, but the latter frequently die suddenly, with symptoms of heart failure, so that as a rule I place more reliance on the amino-acid content of the urine in giving a prognosis, particularly when the output cannot be completely and readily controlled by suitable dieting.

The question of diet is obviously an important one in all cases where amino-acids are found in the urine. It is now generally recognised that many diabetics, and more particularly those of a severe type, do better when the amount of meat taken is strictly limited and intervals of meat-free diet are interposed. This is the basis of the "oatmeal cure," the "potato cure," and similar methods of treatment, and of the vegetable days which are prescribed for most diabetics who are being treated by modern methods. The reason for their use is often not appreciated, however, and they are consequently prescribed in a haphazard manner. Their usefulness really depends upon the different proportions, and to a certain extent the different varieties, of the amino-acids which go to build up proteins of animal and vegetable origin. Animal proteins contain a relative excess of those forms which the defective metabolic powers of the diabetic find it difficult to break down and utilise for purposes of energy production, whereas vegetable proteins are comparatively poor in these constituents as a rule and contain a higher proportion of amino-acids which can be made use of to supply the energy needed by the tissues. Egg protein resembles vegetable protein so far as the diabetic is concerned, so that eggs can be used with safety in many cases where other animal proteins are contra-indicated. The protein of milk comes under the same category as other animal proteins, and one is therefore bound to forbid or strictly limit the use of milk, even when it has been deprived of its sugar, and also the numerous "diabetic" biscuits and bread substitutes which are now largely made of casein in place of the less palatable gluten, by many cases of diabetes

If we find that the urine of a patient suffering from glycosuria contains amino-acids we must first determine whether these are being derived from the food alone or come from the tissues as well, and if the former, whether he is still able to metabolise vegetable and egg proteins satisfactorily. Should the exclusion of animal proteins of all kinds from the diet result in a disappearance of the amino-acids, as it does in most gouty individuals, the prognosis is hopeful, and it is probable that by carefully regulating the diet, especially with regard to the kind and amount of protein taken, we shall be able gradually to improve the metabolic powers and get rid of the glycosuria, or at least prevents its increase. If, on the other hand, the exclusion of animal protein does not bring about a disappearance of the amino-acids, it may be concluded that the case is one in which there are serious secondary disturbances of metabolism, and that, although the life of the patient may be prolonged for a considerable time if a carefully arranged system of dieting is adopted, the condition is likely to grow worse and ultimately prove fatal. Much may be done even for patients whose condition appears to be almost hopeless if the diet is controlled by thorough and regular analyses of the urine. I have several patients under my care at the present time who have been told by physicians whom they had consulted two, and in one instance three, years ago that they had not many months to live in all probability, but they are still alive and comparatively well. The improvement in their condition has been brought about by a careful adjustment of the diet to their metabolic capacity, and a regulation of the protein and fat intake as well as the amount of carbohydrate consumed. In one of these cases the patient gained 23 pounds in weight in the first five months, and in another 28 pounds in six months, after the diet was rearranged. Others have also put on flesh, but not to such a marked degree. I am strongly of opinion that the common policy of allowing patients with glycosuria an unlimited amount of meat is pernicious in all cases, for even when no amino-acids are being excreted in the urine, and it is evident that they are being utilised by the organism, we should remember the high specific dynamic effect of protein foods, and bear in mind that it has been proved experimentally that a purely protein diet stimulates metabolism 40 per cent. over the fasting standard, as compared with 6 per cent for carbohydrates and 14 per cent for fats. A highly protein diet throws work that should be avoided if possible on an already defective organism, and its continuance tends to strain what powers remain to breaking point, with the result that sooner or later amino-acid metabolism fails in most cases, and the third or "true diabetic" stage is reached. The more I see of diabetes the more firmly am I convinced that the diet of even the mildest cases of glycosuria should be regulated by careful and complete urinary analyses and be so adjusted that no avoidable strain is thrown upon the metabolic powers of the patient in any direction. The appearance of amino-acids in the urine in recognisable amounts is usually a sign that too much protein food is being taken, just as the presence of sugar is an indication that more carbohydrate is being consumed than the patient can deal with efficiently. Their persistent increase, in spite of careful dieting, is of bad prognostic significance, but a steady diminution following a regulation of the protein intake suggests that, with care, the life of the patient may be prolonged for months or even years.

Nottingham-place, W.

THE MORTALITY OF CHILDREN FROM BURNING.

BY WILLIAM A. BREND, M.A. CAMB., M.B., B.SC. LOND.,
LECTURER ON FORENSIC MEDICINE, CHARING CROSS HOSPITAL.

THE deaths here examined are those of infants and children from burning caused by ignition of clothing, lamp accidents, and, in the words of the Registrar-General, "otherwise or not stated how," the great bulk of which may be assumed to have been due to the catching fire of clothing. The following are the actual figures for the years 1906 to 1911:—

Ages.	Boys.	Girls.
0 to 1	214	234
1 „ 2	443	466
2 „ 3	840	623
3 „ 4	630	729
4 to 5	368	775
5 „ 10	389	1427
10 „ 15	47	369
15 „ 20	33	261

In the subjoined chart a small correction has been made for the slightly greater number of boys at the earlier ages than girls. It will be seen that there is a very marked difference between the mortality of boys and girls. In the case of boys the figures increase rapidly up to the age of 3, drop nearly as quickly to the age of 6, and then gradually fall away to almost nothing. The mortality of girls continues to increase up to the age of 5, and then declines, though to not nearly the same extent as among boys. It remains higher through the ages of adolescence, being between the ages of 15 and 20 about eight times as great.

This remarkable difference in the mortality is probably due to the difference in the style of clothing worn by the two sexes. Up to about the age of 3 boys are dressed in the same way as girls. From 3 to 4 they are put into male attire and there is an abrupt and marked fall in the mortality from burning. With girls it is not until the age is reached at which they are better able to take care of themselves that the figures show a decline, though even then, and for later years, they remain much higher than those relating to boys.

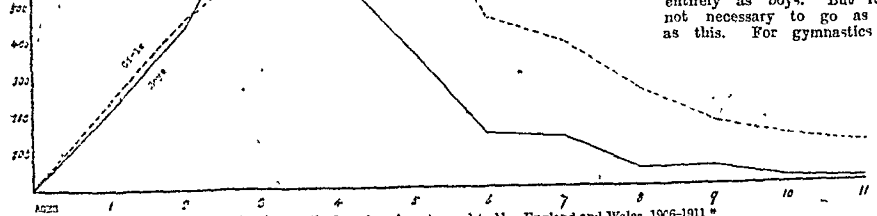

Chart showing deaths from burning at ages 1 to 11. England and Wales, 1906–1911 *

Miss Synge, in her admirable book on children's clothing, has recently drawn attention to the excessive number of garments worn by children of the poorer classes. Speaking of her experience in schools she writes: "The quantity of material used on the children was pitiful. Early Victorian patterns were for the most part used, and underneath the pleats and gathers the children looked swollen and shapeless. ...... The girls are the worst off. First they wear a thick vest and bunchy flannelette chemise. Flannelette drawers over or under some sort of stays—often boned—follow. Then two or three petticoats gathered or pleated into a waistband, or more often attached to a body or two bodies, not infrequently three bodies, of varying sizes. Over this is a bunchy frock, often kilted, and a pinafore. The garments are of varying sizes, some much too tight, some too large, and there is little freedom of limb such as we would see"

Probably no more inflammable arrangement than this, consisting of layers of flimsy material separated by air, could be devised. The corner of a pinafore has only to become ignited and in a moment the little victim is a mass of flames. On the other hand, the inflammability of a boy's costume consisting of cloth knickers and jersey or coat is far less

Considerable agitation has been directed against the use of flannelette, which is very largely worn, and undoubtedly the cheapest varieties are to be avoided. But this material is inexpensive, and it would probably be difficult to substitute anything for it among the poor. The foregoing figures show that it is not so much the material as the style of clothing which leads to loss of life, and probably any other light material used in the present fashion would be almost as dangerous.

The reason for the higher mortality of boys as compared with girls between 2 and 3 is not quite clear, but it may be due to boys at this age being rather more vigorous and enterprising than girls, and more frequently getting into positions of danger. It might be suggested that the higher mortality among girls at later ages is partly due to their being kept more at home and engaged in culinary work. But against this must be set the greater tendency of boys to play with matches or fire.

In addition to its inflammability there are other reasons for condemning the present manner of dressing little girls. The great quantity of clothing hampers the freedom of limb and body, wastes material, adds to the work of the mother in keeping it in repair, and necessitates heavy toil on washing-day. Efforts are already being made in various schools to induce mothers of the poorer classes to dress their children in a more reasonable way, and the Croydon local health authority has issued a sheet containing advice to parents on clothing. It is now a common experience at the seaside to see girls up to the ages of 7 or 8 dressed entirely as boys. But it is not necessary to go as far as this. For gymnastics or drilling a costume is now worn in many schools consisting of navy serge knickers and a short tunic or jersey and plain serge skirt. This costume is becoming, serviceable, and hygienic, and does not subject the wearers to the risk of injury or death in one of its most terrible forms. These are strong reasons for encouraging its use among the poorer classes in every way possible.

ROYAL SOCIETY OF MEDICINE.

SECTION OF PSYCHIATRY.

Pellagra with Insanity.—What is Insanity?

A MEETING of this section was held on Oct. 28th, Sir GEORGE SAVAGE, the President, being in the chair.

Dr. J. W. E. COLE demonstrated a case of Pellagra with Insanity.[1] The patient was a woman who three days after admission to a mental hospital developed an erythema on the bridge of the nose, and this rapidly spread over certain parts of the face. Three weeks later the affected area was covered with a dry, yellowish-brown stain. The scaly surface had a clearly defined red margin, was very symmetrical in distribution, and resembled in every respect a case of severe sunburn. The backs of the hands were deeply pigmented and the epidermis was very rough and coarse. She had a dysenteric form of diarrhœa, but no stomatitis. Her reflexes were definitely exaggerated, but ankle clonus was absent. Her mental condition was difficult to distinguish from dementia præcox. The rash was now disappearing, and with it the mentality was improving. She had been in the asylum, on and off, four years, but the rash had not previously appeared.

Dr. CHARLES A. MERCIER read a paper entitled "What is Insanity?" He said there existed a vague notion of what was meant by insanity, but the fact that this notion had not been satisfactorily reduced to words showed that the concept was unprecise. Insanity and unsoundness of mind were not convertible terms. Each included much which was not in the other; in fact, the two things coincided for only part of the way. Insanity was a disorder not only of mind but of conduct; giddiness, epileptic auræ, claustrophobia, and agoraphobia had nothing to do with insanity. No one dare call a man insane until he had examined his conduct and found it disordered. And in speaking of disorder of conduct he did not mean "disorderly conduct" in the police court sense. But disorder of brain function might be added to the concept, making it a threefold matter; also disorder of metabolism deserved a place, making it fourfold. Each of these concepts was right in its own connexion; confusion ensued from giving all the concepts the same name. If insanity meant disorder of conduct and mind alone, then insanity was a symptom of disorder of brain function. If insanity meant disorder of conduct and mind *plus* disorder of brain function, and if these three were correlated disorders from which the patient suffered, then the three disorders constituted the disease insanity. But if these three were correlated with some wider disorder, such as alcoholic poisoning, myxœdema, gout, specific fever, Graves's disease, this threefold disorder was a sub-disease of the wider disease. When insanity was a symptom only he argued that it was expedient to speak of it as delirium, reserving the name "insanity" for cases in which what was meant by it was a disease

The paper was discussed by the PRESIDENT, Mr. JAMES STEWART, Dr. PERCY SMITH, Dr. ERNEST JONES, and Dr. E. S. PASMORE, and Dr. MERCIER replied, elaborating his thesis still further.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Chronic Abdominal Pain.

A MEETING of this society was held at the Royal Devon and Exeter Hospital on Oct. 10th, Dr. C. J. VLIELAND, the President, being in the chair. In response to an invitation from the council of the society an address was given by Mr. T. CRISP ENGLISH, who had chosen for his subject "Chronic Abdominal Pain." Mr. Crisp English dealt mainly with the cases in which the cause of the pain was not at first obvious, and in which the question of a laparotomy usually arose. He said that these cases were becoming increasingly common, both in private and in hospital practice. The private patient who had had attacks of pain for some time, in spite of various forms of medical treatment, was sooner or later sent to the surgeon for an opinion; hospital patients were constantly arriving with notes saying that the bearers had had a chronic pain and advising that they should be opened. There was no group of cases in which good sound judgment and common sense were more needed. On the one hand, many patients might be saved years of chronic abdominal pain and ill-health by operation; on the other hand, many patients had been plunged into hopeless invalidism by an ill-considered laparotomy. Speculative operations frequently led to disaster, and were often the forerunner of further operations upon patients who never seemed to get well and who were always ready to have yet another organ explored or excised; but in most cases of chronic abdominal pain there was a definite organic cause for the pain, which could be removed by operation, and if the effects of the pain justified operative measures, then operation should be advised. The most important point was that a thorough physical examination must be made before the best line of treatment was decided upon. Not until evidence of every possible kind had been collected and summarised should diagnosis and treatment be discussed. In this the surgeon must rely upon the coöperation of the medical practitioner and the physician. In hospital practice the diagnostic process was easily arranged, and the following was the usual procedure, say in the case of a patient who had chronic or recurrent abdominal pain, the cause of which was not at first obvious. The history of the case was carefully taken, and the usual physical examination made. The urine was measured for 24 hours and analysed. If there was any doubt about the kidneys or bladder a bacteriological examination was made, for a coli pyelitis was the cause of some cases of obscure pain in the side. Skiagrams were then taken, either of the urinary tract to exclude stone, or of the alimentary tract after the ingestion of a bismuth meal. The patient was referred to the physician in many cases; in doubtful stomach cases a test meal was given and the result analysed. In certain other cases also special investigations were carried out, such as examination with the sigmoidoscope or cystoscope or a blood examination. Further, there might be a difficulty in properly examining the abdomen or pelvis, and an examination must be made under an anæsthetic. There should always be clear definite reason for an examination under an anæsthetic, and it should never be done on the off-chance that something might turn up which could not be discovered without it. The various reports and analyses were brought together after three or four days and these clinical findings were considered as a whole. In this way the diagnosis and treatment could be discussed under the best possible circumstances. Wealthy patients might also have a thorough investigation, but the man of moderate means often could not enjoy the advantages open to the rich and poor, and in his case the question of expense very often meant a limited investigation; this was obviously a matter which urgently needed reform. In taking the history of the illness, the important point was to be quite clear as to the very beginning of the illness: when was the patient last in quite normal health? what was the very first symptom he noticed? The initial symptoms should be gone into carefully and fully, and these would often suggest a clue which could not be picked up in the latter part of the history. The examination of the abdomen should never be hurried. They should look and think before they felt, especially in children. The well-known picture of "The Doctor," by Sir Luke Fildes, expressed perfectly what should be the attitude of the medical man towards the sick child: watching and thinking, and realising that much might be learned whilst the child slept. Skiagrams of the alimentary tract might give very valuable information, but one must confess that in the bulk of cases of chronic abdominal pain they were apt to be disappointing. A great deal had yet to be learned about the meaning of the skiagraphic appearances. Deductions made from skiagrams were often falsified when the abdomen was opened, and skiagrams should only be considered in conjunction with other means of investigation. In reviewing the cases of abdominal pain one noticed at once that there were certain well-marked types and groups. There was the gastric group of cases; there were the men with pain in the right upper abdomen; there were the women with pain in the right side; there were those with suspected appendices; there were the elderly, who might have malignant disease; there was that big distressing group of cases whose trouble and often never ended was colitis; and, of course, there were the children in a well-marked group of their own. As regards the gastric group, an important point to remember was that the surgeon should be very wary of exploring the stomach of a patient who did not vomit, however large and splashy the stomach might be, and whatever the skiagrams appeared to show. If, however, there was any suspicion of malignancy, that patient must not be left until the matter was cleared up. Chemical examination of the stomach contents would usually give definite information. Concerning the women with pain in the right side, there were certain points well worth bearing in mind. Gall-stones were unlikely to be present unless there was pain in the back; 20 per cent. of women had some degree of mobility of the right kidney; if a patient was told that she had a movable kidney she would never forget this fact. Trusses and pads applied in the hopes of supporting a mobile kidney often pressed injuriously on the cæcum, damaged the appendix, and so produced a new cause of abdominal pain. One of the greatest harms that could be done to a patient was to tell her that the pain was connected with the ovary; such a statement had often started a condition of chronic introspection, leading to mental and bodily ill-health. In the large group of cases in which the appendix was suspected there were two quite distinct classes. Firstly, these were the cases in which there were mild recurrent attacks of pain and uneasiness, which might be due to slight inflammation of the appendix; and secondly, there were those in which there was chronic inflammation of the appendix producing constant uneasiness in the abdomen and general ill health. The two conditions might be combined, but the difference between them must be clearly remembered. In the former, if a diagnosis was made of mild attacks of appendicitis, the only wise plan was to have the *appendix removed unless there was some good reason to the* contrary. He did not suppose that many would dispute this statement nowadays. Under modern conditions the risk of appendicectomy was a long way below a half or even a quarter per cent.; on the other hand, a diseased appendix [illegible] Definite localised tenderness, [illegible]ssed off, was usually the sign [illegible] and the man who had pain to-day and tenderness in the right iliac fossa to-morrow had a diseased appendix. Chronic appendicitis was the greatest surgical discovery of recent years, but the disease was surrounded by a host of base imitations, and the surgeon must pick his way carefully when dealing with this subject. No patients were more satisfactory or more grateful than those who had had a chronic diseased appendix removed. The subject of chronic appendicitis had usually been out of health for some time; he was a man who ought to be well and healthy but was not. In a well-marked case the digestion was disordered; pain and distension followed the taking of food; the action of the bowels was erratic, usually constipation with bouts of diarrhœa; tongue furred and breath unpleasant. The abdominal unrest reacted on the general health, which soon suffered. In such a case, if definite evidence of trouble about the appendix was found, a diagnosis might be made of chronic appendicitis, and operation would assuredly restore the patient to good health and enjoyment of life. The full benefit of operation was not always apparent at once and careful after-treatment was essential, but the ultimate results were excellent. The colitis group of cases presented great difficulties. The majority of the patients, unfortunately, could get no help from surgery. For many of them, in fact, the worst thing that could happen was that they should be operated upon. But there was a definite group in which the trouble was associated with an infected appendix. There was no doubt that in certain cases the appendix was the primary focus of infection, and the patient could not be got well by medical means until after the appendix had been removed. The most careful judgment was necessary, for removal of a [illegible] to a cure, whilst, if the [illegible] of the appendix was [illegible] should be decided upon, one point was of great importance: never lead the patient to suppose that removal of the appendix would see the end of all her troubles; operation must be regarded as a preliminary step in a complete scheme of treatment. In children the great majority of cases of abdominal pain were due either to disease of the appendix or to tuberculosis of the lymphatic glands. One of the most striking revelations of abdominal surgery was the frequency of glandular disease in the mesentery. It was a most *unfortunate thing for the children of this country* that the overcrowded programmes of the Parliamentary sessions prevented the passage of Bills for the control of milk-supply and the inspection of dairies. One of the results was the frequency of abdominal tuberculosis. Chronic appendicitis in children was a very definite disease, and Mr. Crisp English believed was at least as common as acute appendicitis. The text-books contained a scanty reference to this chronic condition, for it was only in the last two or three years that it had emerged from the obscurity of the intestinal disorders of childhood. In the earlier days of appendicitis there was a disinclination to operate upon children in the quiescent stage, unless there had been at least one definite and severe attack. Later clinical observation showed that some of the children with disordered abdomens and unsatisfactory health had, from time to time, attacks of pain and tenderness about the appendix. Removal of the appendix brought about a remarkable improvement in the general health, and so it gradually became clear that these children had been suffering, and suffering very decidedly, from chronic appendicitis. As time had gone by the improvement had been maintained. The children operated upon three or four years ago had never turned back. This was convincing that the appendix was beyond all doubt the cause of ill-health. Once the medical man felt sure about the diagnosis he should advise operation, and this for two reasons. One was that the child would not get well until the appendix was out, and the other was the ever-present risk of an acute attack. Acute appendicitis was one of the worst catastrophes that could befall a child, and once a child's appendix had shown signs of *inflammation it should come out. Remove the appendix and* the health would at once improve; good spirits and appetite were regained, and the child was once more what Nature meant that child to be.

---

[1] THE LANCET, Sept. 6th, 1913, p. 717.

At the conclusion of his address a hearty vote of thanks was given to Mr. Crisp English on a proposal by Dr. D. W. SAMWAYS, seconded by Mr. RUSSELL COOMBE.

Mr. Crisp English was subsequently the guest of the society at the Exeter and South-Western medical dinner.

LIVERPOOL MEDICAL INSTITUTION.

Aseptic Technique of the Anæsthetist.—Enucleation of the Tonsil.—Suppurative Diseases of the Labyrinth.

A MEETING of this society was held on Oct. 23rd, Mr. ROBERT JONES, the President, being in the chair.

Dr. G. F. R. SMITH read a note on the Aseptic Technique of the Anæsthetist, in which he insisted on the preparation of [illegible] overall, cap, mask, and gauntlets.—Mr. R. C. DUN spoke of the advantages of the method, *especially in operations* on small children, where the anæsthetist was of necessity close to the field of operation.

Mr. THOMAS GUTHRIE read a note on Enucleation of the Tonsil. Referring to the technique of the operation he preferred the guillotine operation, introduced by Sluder in America and Whillis and Pybus in this country, for the great majority of cases. The method, however, failed in a few cases of very adherent tonsil, and in *these he employed* blunt dissection and a snare. Discussing the indications for the operatio[illegible]
cases of pur[illegible]
sillotomy wa[illegible]
more than t[illegible]
left behind. [illegible]
was almost always sufficient, and was a less severe operation than enucleation. Bleeding *after the two operations* was as [illegible] more [illegible] after [illegible] had [illegible]rming [illegible] the portal of entry for g[illegible] infection,

enucleation was the only scientific and satisfactory operation. Lantern slides and specimens of tonsils and the instruments used were shown.—Dr. W. SANDERSON, Mr. J. BARK, Mr. C. YORKE, Mr. E. M. STOCKDALE, Mr. A. ADAIR DIGHTON, and Mr. W. THELWALL THOMAS took part in the discussion.

Mr. ADAIR DIGHTON read a paper on Observations on the Diagnosis of the Suppurative Diseases of the Labyrinth. After reminding members of the fact that one of them, Dr. Edgar Stevenson, had introduced labyrinthology into England as far back as 1896, Mr. Adair Dighton demonstrated the tests upon a patient by means of the instruments of Brüning. He then took up in detail the various pathological divisions of labyrinthitis, together with the treatment of them. This completed, he went into the differential diagnosis between labyrinthitis, cerebellar abscess, meningitis and tumour of the auditory nerve. To wind up, he was of opinion that no operation, however small, should be undertaken upon the ear without the preliminary application of the functional tests.—Dr. PANTLAND HICK spoke of a case in which he had been associated with Mr. Adair Dighton where a successful differential diagnosis of cerebellar abscess had been made by the Brüning tests.—Dr. W. B. WARRINGTON said that whilst the nervous mechanism of the vestibular nerve and its relationships to the Deiters group of cells and oculomotor muscles were clearly known, the manner in which different kinds of stimuli excited the several semicircular canals and so caused nystagmus in different directions was difficult to follow, so as to be able to apply readily in practical work. Further simplification of the technique was desirable, especially when it was necessary to examine persons who were ill with intracranial complications. Dr. Warrington alluded to the rarity of cerebellar abscess compared with suppurative disease of the labyrinth, and urged the importance of diagnosis *inter operationem*.—Mr. STOCKDALE said that suppurative middle-ear disease attacked the labyrinth in two positions: (1) the region of, the promontory; and (2) the external semicircular canal in the region of the antro-tympanic passage. Total deafness on the affected side would suggest invasion in the cochlear region, and if the auditory apparatus was intact the application of the caloric test would decide whether the semicircular apparatus were active or not. If an erosion of the external canal was found during operation it was usually advisable not to interfere with it. The radical mastoid operation on rare occasions was performed on patients suffering from meningitis. A preliminary lumbar puncture was most helpful in doubtful cases. Deaths from meningitis following a radical mastoid operation and due to lighting up a latent labyrinthitis, although it might occur, was extremely rare.—Dr. EDGAR STEVENSON and Mr. HUGH E. JONES also spoke, and Mr. ADAIR DIGHTON replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Need for Eugenic Reform.

A JOINT meeting of this society and the Edinburgh Obstetrical Society was held in the hall of the Royal Victoria Dispensary on Oct. 29th to hear an address by Major LEONARD DARWIN, President of the Eugenics Education Society, on "The Need for Eugenic Reform." In introducing the subject Major Darwin said that Linnæus, writing in the middle of the eighteenth century, declared that species were now as numerous as when Providence first created them in the beginning, and that, in accordance with the laws of generation then laid down, the beings originally created produced only forms similar to themselves, with the result that the species now with us were no more numerous than they were at the first. In writing this, this great naturalist was only expressing his belief in the immutability of the different forms of life almost universally held in all civilised countries until the middle of last century. It was true that the suggestion that the world was the outcome of a long series of continuous changes had been made by several philosophers in ancient days; whilst from time to time some more advanced thinker would express the belief that every animal, including man, was the lineal descendant of some more primitive type of living thing. But those who held such views were always so few in number that the general acceptance of their beliefs could only be described as a complete revolution in thought. But must not the adoption of the belief that by evolution alone could we account for the visible facts of life tend to produce material alterations in the way in which we regarded many practical questions? The truth was that it was quite impossible for us to go on acting as if we held precisely the same beliefs as our ancestors, and the aim of the eugenist was both to guide and to hasten the reforms in social customs and in legislation which must in any case result from the acceptance of the doctrine of evolution. Anyone who studied our Poor-law statistics or who looked at our ever-growing lunatic asylums, homes for imbeciles, and hospitals, or who considered our criminal records, or who merely took a single walk in our city slums, must feel profoundly dissatisfied with the existing social conditions of his country. Splendid efforts were no doubt being made on all sides, but when we remembered how long this noble strife had lasted we were absolutely driven to inquire whether some other and hitherto untried methods were not also essential to secure the progress of the nation, or indeed to safeguard it from decadence. If, as Major Darwin held, it would be necessary to continue in the future, as in the past, to try to alleviate or mitigate the sufferings of our fellow creatures by the application of immediate remedies, it would be absolutely incumbent to recognise the necessity of searching for the ultimate sources of all these evils. In the past the efforts of the social reformer had been almost entirely directed to conferring immediate practical benefits on man by altering his mental and physical surroundings. We must, however, also in the future endeavour to ensure that our descendants shall actually enter the world with a better natural equipment than that which we possess. As long as complete ignorance prevailed as to the way in which the generations of man succeeded each other, it was inevitable that all philanthropic efforts to help the human being should have begun at his birth. Now that this ignorance was being dissipated we were bound to see if something could not be accomplished before his birth, and that was the aim of the eugenists. They held that the world was so constituted that all the good qualities of man, as well as all his evil tendencies, had been evolved in accordance with what were called the laws of nature. Their hope and belief was that by studying these laws we should now be able to take steps tending to ensure that the man of the future should be a far nobler being than the man of to-day. Major Darwin said that eugenists were not yet in a position to formulate a policy with great precision. They, however, saw clearly that the selection of the ancestry of the coming generations had been one of nature's main methods of ensuring racial advancement. Nature had always paid the closest attention to heredity, and this study was imperatively imposed on them. It was essential to adopt reforms based on heredity. The breeders of racehorses did not quarrel as to which was the more important for their horses, good training or good pedigree; and the breeders of mankind should not wrangle as to which was the more important, environment or heredity. There was much for eugenists to do, and he rejoiced that a eugenic society was likely to be formed in the capital of Scotland. Galton's definition of the science was that it included "the study of the agencies under social control that may improve or impair the racial qualities of future generations, either physically or mentally." The evil effects of alcohol on the drinker and his family were unquestionable, but how the distant descendants would be affected was unknown. As to the campaign against drink and disease, the eugenist should take part in it. The same was true with regard to environmental reforms, such as better housing and sanitation. But pending further knowledge as to the ultimate effects of all such reforms, if they wanted to ensure the progress of the race they must not confine their efforts to the cure of these evils, but must also consider the factor of heredity, which was the key by means of which the door leading to the future advancement of mankind could be unlocked. Their main object should be to decrease the rate of multiplication in the lower strata of humanity relatively to that in the higher strata. The poorest classes contained many individuals both very virtuous and very capable, whilst amongst the rich many most undesirable specimens were found. A sorting process was always going on, the naturally able amongst the poor often acquiring greater wealth, whilst many of the naturally deficient amongst the rich slowly sank from their more comfortable estate. The poorest strata did contain an exceptionally large proportion of the biologically unfit, but also had an exceptionally high birth-rate. If this meant that the unfit were multiplying more quickly than the fit, the nation was decadent. Speaking of the remedies for the relatively low rate of multiplication of the more capable classes, he suggested the income-tax being made to vary according to the size of the family, and death duties also. The pay of State employees might be made partly dependent on the number of their children. Such expedients would touch but few, and their main hope must rest on changing the mental attitude of the whole nation with regard to the duties owed to posterity. As to the high fertility of the very unfit, little could be done to check it by moral persuasion. A class did exist, out of which a vast output of undesirable citizens was taking place, which could only be dealt with by sterilisation or segregation. As to the former, he would only say it was a question to be approached with the utmost caution and in a very conservative spirit. They should watch what was taking place in America. As to segregation, this was in the region of practical politics since the passing of the Mental Deficiency Bill, which his society had no hesitation in placing in the forefront of their programme. But besides the feeble-minded other classes of degenerates—e.g., criminals and paupers—ought to have the rate of their multiplication diminished. Habitual criminals and paupers judged to be truly degenerate should be dealt with, not as needing punishment, but as requiring protection against themselves or for safeguarding the public from present injury and future hereditary taint. Their periods of confinement should never be short. Such a system would reduce the output of defectives, and this was all they could hope to do at present. In strengthening the scientific foundations of eugenics much remained to be done. A moral superstructure required to be erected, and here he was convinced their greatest difficulties would arise. Their main object must be to sow [illegible] deep and impelling sense [illegible] Eugenic education socie[illegible]laces, for everyone who [illegible]onsciously induced to become an advocate in their favour in general conversation. At Liverpool certain members of the council of the local Eugenic Society had done excellent service in giving elementary lectures in eugenics at various institutions, and, again, help was needed in making the best use of the local press, and lastly, special efforts should be made to interest teachers in schools in their cause. If the eugenic ideal could be properly planted in the minds of all children, not only would the effect be immediately ennobling, but good fruit would in time grow out of this seed by the men and women of the future. In concluding, Major Darwin said that it was not only the help of the scientist and the moralist that they needed, but every class was required to fight against national degeneracy. If it were only more widely known how enormous was the burden thrown on the community by the vast number of degenerates the need for reform would be better understood. Increased taxation, lowered wages, increased prices, diminished aid in time of trouble, and lessened power of competition in time of peace, these were the penalties we were now paying for the carelessness of our ancestors with regard to the purity of our race. Should we pass on this taint with undiminished intensity to posterity? If they could make the facts on which their creed was built more widely known, he was certain they would only have to appeal to their fellow countrymen to attract sufficient recruits to make the success of their cause a certainty

Sir THOMAS S CLOUSTON said that Major Darwin's address would give them a stimulus to start a eugenics society in Edinburgh. He was in thorough sympathy with the movement, and said there was no doubt that they had no possible hope of checking the increase in a large number of the mentally defective except through eugenics.

Professor J. COSSAR EWART said those of them who had been interested in questions of heredity were all prepared to help in the formation of such a society as had been suggested. The time must come in the history of all nations when extravagance must come to an end. Hitherto he thought they had been extravagant with their people, and they had not done much to encourage the fit.

Dr. D. BERRY HART said there was a great field for eugenics, and while he agreed in many points with Major Darwin, undoubtedly there were a good many difficulties. For instance, there was a great ignorance as to the laws which determined people to marry. They knew that the marriage of apparently suitable persons did not always turn out very well and that genius was not transmitted. He was exceedingly glad that Major Darwin had given them such a cautious and sane address, but one felt that it was one of the most difficult subjects in the world.

Dr. R. D. CLARKSON (Larbert) also spoke.

Major DARWIN having replied, a provisional committee, with Sir Thomas Clouston as convener, was appointed to take steps with a view to the formation of a eugenics society in Edinburgh.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the session was held on Oct. 24th, Dr. T. Wardrop Griffith, the President, being in the chair.—The President gave an introductory address on the Development of our Knowledge of Diseases of the Heart. He commented on the necessity for those who were working at the newer methods of cardiac investigation to turn at the same time to the work of the older observers, and he passed in review some of the main contributions to our store of knowledge found in the works of Morgagni, Senac, Alan Burns, Corvisart, and Laennec, and among more recent observers John Elliotson, James Hope, Corrigan, and, among the Victorians, Gairdner and Balfour. As a practical result of the employment of the methods of experimental physiology we now had, as aids in our clinical work, the polygraph of James Mackenzie and the electrocardiograph of Einthoven. From former demonstrations the members of the society were more or less familiar with the former of these two instruments; the principles of the latter were explained and reference was made to the valuable work of Dr. Thomas Lewis, who had in this country probably done more than anyone else to advance the utility of the instrument. The address was illustrated by a large number of lantern slides.—The following cases and specimens were shown: Mr. G. Constable Hayes: A case of Syphilitic Disease of the Tonsil, with Glandular Enlargement, Simulating Sarcoma.—Mr. Walter Thompson: A patient with Extensive Rodent Ulcer of the Shoulder.—Dr. W. H. Maxwell Telling and Dr. E. O. Croft: Heart showing large Valvular Clot and Suppurative Pericarditis; Uterus with recent Septic Abortion; (?) relationship between the septic process and the clot; death by pulmonary embolism.—Dr. M. J. Stewart: Section from a case of Myeloid Sarcoma of a Tendon Sheath.—Cases were also shown by Mr. S. W. Daw, Dr. C. W. Vining, Dr. A. L. Whitehead, Mr. J. A. Coupland, and others.

EXETER SANATORIUM FOR TUBERCULOSIS.—This sanatorium in connexion with the Exeter Insurance Committee, was opened last week. The building, which was formerly the Heavitree isolation hospital, will provide accommodation for 12 patients.

NATIONAL HEALTH SOCIETY.—This society is organising a number of courses of instruction which will be given from November until April of next year. At 53, Berners-street, London, W., the offices of the society, there will be courses for women training as sanitary inspectors and health visitors, and also for voluntary health workers among the poor. Private courses in drawing-rooms will be given on first aid, nursing, and personal hygiene, and lectures will be delivered at mothers' meetings, working men's clubs and institutes, and girls' friendly societies on all subjects relating to health, the feeding and general well-being of mothers and infants, boys and girls, and the sanitation of the domestic household. The Lady Priestly Memorial lecture for the year will be given by Professor William Stirling, M.D., on Nov. 27th, at the Royal Society of Medicine, the subject being "Health, *Fatigue, and Repose*" A course of 12 lectures on Tuberculosis by Dr. J. E Squire, C.B., was begun on Nov. 3rd at the offices of the society. Applications relating to these lectures should be made to the secretary.

Reviews and Notices of Books.

Die Rassenhygiene in den Vereinigten Staaten von Nordamerika. By Geza von Hoffmann. Munich: J. F. Lehmann. 1913. Pp. xxi.-237. Price 4 marks.

State Laws Limiting Marriage Selection, Examined in the Light of Eugenics. By Charles B. Davenport. Long Island, N Y.: Eugenics Record Office. Bulletin No. 9. Pp. 66. 1913. Price 40 cents.

As is well known, America is the country where experiments in legislation for eugenic and other social purposes have been chiefly made, but hitherto there have been no convenient handbooks to which one could refer if in quest of information on the subject. This want has now been supplied by Herr von Hoffmann, who, as the Austrian vice-consul in California, was in a favourable position for collecting the necessary information. But he has not confined himself to a description of the legislative enactments of the Union or of the various States. He has also taken pains to master, as much as possible, what has been said and written for and against them, whether they deal with sterilisation, limitations in marriage, or the selection of immigrants, and with regard to each question involved he has made a clear summary of the *pros* and *cons.* Also to make his book more useful to persons quite unfamiliar with the subject, he begins with a chapter on the principles of race hygiene, but it is questionable whether his treatment of such subjects as the germ-plasm and Mendel's laws is not altogether too brief to be intelligible to a beginner. English readers in any case will have little use for it. More valuable is the next chapter, which describes the agencies concerned in the spread of eugenic ideas in the United States; but perhaps the most useful feature of the whole book is the bibliography which occupies the last 80 pages.

Dr. Davenport's work is of an entirely different nature; its most valuable part is the appendix, which contains a digest of the State laws limiting marriage selection. Their examination in the light of eugenics will hardly serve as a guide for future legislation on the subject, as the method adopted is the simple enumeration of the results of the various kinds of matings which are prohibited in one place or another. For example, with regard to incest between brother and sister, two cases are recorded: 1. "Hannah, about whom nothing is known (except that she has the reputation of not having good sense) had by her brother William, of whom also nothing is known (except that he was a painter) a son .. . . of whom someone said he is 'very feeble-minded,' while others have said he is not so bad considering." 2. "The father is feeble-minded—son of an alcoholic criminal. By his sister, who is mentally defective, he had a daughter who is epileptic, alcoholic criminalistic, and without sex control."

What light these two cases throw on the question whether brother and sister marriages are biologically desirable or not, or what use at all it is to discuss the question, it is difficult to see; nor is it easier to follow how by recording the following solitary case any help is given in deciding whether great-uncles and nieces should be allowed to marry. The case is that "Emily R., when 13 years old, was married, for a monetary consideration, to her father's father's brother, who was then 51 years of age. They had three children, of whom the eldest was sexually immoral and died of paresis at 42 years; one boy was 'not bright,' and was drowned at 18 years; the youngest boy died at 2 years."

It must be said in fairness to Dr. Davenport that the treatment of the more urgent question of cousin marriages is far more satisfactory, though the conclusion here arrived at is also based merely on quite a few selected marriages; these are arranged to show that desirable results ensue when the husband and wife sprang from a desirable strain, and that the reverse is the case when the stock is tainted.

Protein and Nutrition: An Investigation. By Dr. M. Hindhede. London: Ewart, Seymour, and Co., Limited. Pp. 201. Price 7*s.* 6*d.* net.

There is no date on the title-page and the preface is dated 1913, but in that preface it is admitted that the bulk of the present volume was written in Danish in 1905. The author is superintendent of a State laboratory in Copenhagen, where the practical data contained in the book have been worked out, with the coöperation of five assistants. The author admits in his preface that the book is somewhat polemical in character, an admission which will be readily endorsed by every reader.

The volume claims to be an examination of such authorities on dietetics as Voigt, Hirschfeld, Chittenden, and McKay, and the work of each is surveyed in separate chapters. Towards all these investigators, well known to the whole world for their patient efforts in experimental physiology, Dr. Hindhede adopts an attitude of criticism which would carry greater conviction if it were less confused and more controlled. Copious references are given in footnotes, but their value is seriously lessened by the almost complete absence of dates. When we find that some of the literature referred to dates back to 1879, and is alluded to side by side with the results of quite recent work, it is evident that no attempt at sustained analysis is being made. The author singles out Professor McKay for special attack, accusing him of "confusion" of thought, but he has clearly not studied Professor McKay's complete work published in 1912, which embodied the various papers, admittedly tentative, from which the matter is taken for discussion in the volume before us.

The author's own experiments on himself and his laboratory assistants have been on too small a scale to carry much weight, and, like so many of these experiments, they are carried out on selected subjects, losing sight of the possibility that in a population of varying physique, and varying hygienic surroundings, a mixed dietary may be of value.

Physical Diagnosis. By Richard C. Cabot, M.D., Assistant Professor of Medicine in Harvard University. Fifth edition, revised and enlarged, with 5 plates and 268 figures in the text. London: Baillière, Tindall, and Cox. 1913. Pp. 519. Price 15*s.* net.

A thorough and practical knowledge of the methods of physical examination and of the significance of the data obtained by them is essential to the practitioner, as affording him some of the most important material on which to base his diagnosis. Instruction in this subject is, therefore, one of the utmost importance for the student. Dr. Cabot's book, which has now reached its fifth edition, has achieved a recognised position as a standard manual upon the subject. In our reviews of some of the former editions we have referred to the practical and eclectic character of the information given, and these features are maintained in the present one. Dr. Cabot does not describe any method of examination with which he has not had practical experience. He devotes himself to physical examination proper, and deprecates any distinction between clinical diagnosis and laboratory diagnosis. He prefers to consider all the methods together, and advises that the student should be accustomed to think of them and practise them in close relationship to one another. For this reason he includes descriptions of the analysis of the gastric contents, of the blood, and of the urine.

The arrangement of the subject matter is convenient and simply worked out. Data relating to the body as a whole, such as alterations in weight and variations in temperature, are first considered, and then the various regions, systems, or organs of the body are separately discussed. The information obtainable by percussion and auscultation is very thoroughly described in connexion with the examination of the heart and lungs. Dr. Cabot often gives some valuable statistics in support of the statements he makes. We know of no book in which these methods are more clearly described or in which the significance of the signs obtained by them is more critically discussed.

Among the additions to the present edition we may mention the sections upon arteriograms, phlebograms, and [illegible] Dr. Cabot here only gives a brief [illegible] r obtained from them, and does [illegible] as to the methods of obtaining them. He also gives more details in regard to the arrhythmias in the light of recent work upon their nature. In connexion with the examination of the pulse he devotes special attention to the subject of blood pressure and to the instruments for measuring it. The examination of the stomach by means of the X rays after the administration of a bismuth meal is adequately dealt with, and some reproductions of radiograms illustrating the results obtained are given. The subject of interlobar empyema is well described and is illustrated by a very good reproduction of a radiogram of a case observed by Dr. Englebach and Dr. Carman.

The book is well produced and clearly printed. The number of the illustrations has been increased, and their quality has been greatly improved. They now form a valuable addition to the usefulness of the book. We can commend it to students and practitioners as a reliable and interesting work upon an important subject.

Massage, its Principles and Technic. By MAX BÖHM, M.D. Berlin. Edited with an introduction by CHAS. F. PAINTER, M.D., Professor of Orthopædic Surgery at Tufts College Medical School, Boston. *Illustrated.* London and Philadelphia: W. B. Saunders Company. 1913. Pp. 91. Price 7*s.* 6*d.* net.

IN his introduction the editor states that "physical therapeutics in all its forms is employed far more widely in Germany than in America." It is probably employed far more widely in America than in England. The profession at large are not securing for their patients the benefits that they might, because they do not know enough of the advantages to be gained from massage and exercise to think of making use of such measures, nor are the principles which underly the use of exercises in surgery at all widely appreciated. We are glad, therefore, to see the present large output of books upon this subject. They differ little from each other in their contents, but they all tend to make more widely known the good effects that can be obtained from the skilful application of massage in numerous affections.

We are in entire agreement with Dr. Böhm when he says that in a great many cases, in order to avoid harm, massage should be carried out by the surgeon himself or under his eye; such cases are especially those of inflammatory conditions of muscles, tendons, joints, and nerves, massage of internal organs, the eye, the larynx, &c. But there is unquestionably a large field open to the masseur with *no special medical knowledge*, as, for instance, when massage is administered to practically sound parts to strengthen them or improve their nutrition. The skilled masseur equipped with a small knowledge of anatomy is fully equal to this task. The book under consideration deals only with the latter class of case It is intended for the student who desires to assist the surgeon in an intelligent manner in massage and gymnastics The technique described is essentially that prescribed in Professor Hoffa's clinic After a description of the preparation of the patient and the fundamental manipulations of massage a few general contra-indications are given, and then follow a systematic description of massage as applied to each of the joints, to the groups of muscles in the trunk and limbs, a chapter on the massage of the nerves and skin, and finally on body massage. Coming from the clinic of Professor Hoffa it is unnecessary to state that the methods described are of the most approved and scientific. The arrangement of the subject is the best that we have seen, in that the contra-indications as applied to each joint are clearly stated at the beginning of each section; then follows an equally clear statement of the indications and the most suitable technique for the joint in question. The illustrations, upon which the book so largely depends for its value to practitioners and those unfamiliar with massage, are clear, simple, and well reproduced

We can recommend this book, which from its moderate cost and wide usefulness deserves to find a large public in this country.

The Surgery of the Eye. By ERVIN TÖRÖK, M.D., Surgeon to the New York Ophthalmic and Aural Institute, &c.; and GERALD H. GROUT, M.D., Assistant Surgeon to the New York Ophthalmic and Aural Institute, &c. With 509 original illustrations, 101 in colours and two coloured plates. London: Baillière, Tindall, and Cox. 1913. Pp. 507. Price 18*s.* net.

THIS is in appearance a sumptuous work, with all the superficial attractions of good print and profuse illustrations. Closer acquaintance with the contents, however, proves disappointing. We find that the inflated number of illustrations is largely due to repetition of the same blocks. It is true that these are good—as good as any photographs of operations from nature that we remember to have seen; but photographs from nature are on too small a scale to be satisfactory guides to students, and it is impossible by these means to obtain that sharpness and accuracy of detail which are all-essential in operations upon the eye. The authors appear to have realised this point, for they have added many good diagrams.

With the letterpress we are disappointed Not that there are many actual errors—we have come across only one bad recommendation, viz., paracentesis of the cornea for acute inflammatory glaucoma (p. 175). The great fault is that the operations are not described in sufficient detail. The book is intended as a treatise on ophthalmic surgery for students and practitioners, and as such it ought to emphasise those minutiæ of technique which are more important in this than in any other branch of surgery. This lack of attention to the small details of every step is the besetting sin of the now numerous text-books on ophthalmic surgery. The great book on this subject yet remains to be written. The authors have used the designations "European" and "American" to distinguish the methods of operating from before and from behind the patient respectively. They are apparently unaware that nearly all English surgeons adopt the so-called "American" method, and that the so-called "European" method is by no means universal on the Continent. Most of the ordinary operations are described and instruments are illustrated.

Statistical Ready Reckoner. By GERARD C. TAYLOR, M.A., M.D. Cantab., D P.H., Medical Officer of Health of Berkshire. Reading: Bradley and Sons 1913. Pp. 409. Price 12*s* 6*d.*

PRESUMABLY this book is intended for the use of junior members of the Public Health Service, or of others whose leisure is so limited as to render such a *vade mecum* serviceable. The value of the set of tables that form the bulk of this volume has been proved by the author, who has used them in calculating the statistical rates required in his own work as county medical officer of health of Berkshire; and he publishes them with a view of facilitating the arithmetical labour of others similarly circumstanced.

The tables are prefaced by a set of examples showing how the former may be used most expeditiously. These examples appear to be correctly worked out, and the ready reckoner may be serviceable to those who are not familiar with the use of the ordinary logarithmic tables. We have not examined the 400 pages of tables that form the bulk of this volume, but the author affirms that great care has been taken, both in their preparation and in the correction of the proof-sheets, and trusts that no serious errors have been overlooked. The following suggestions are offered to those using the ready reckoner for the first time. In the first column of each page the population numbers in the tables are arranged consecutively, the figures in heavy type printed at the head of the other columns indicating the number of events (births, deaths, &c.) corresponding to the rates per 1000 of the population. In order to keep the volume within convenient limits the populations above 10,000 have not been included; but inasmuch as the rates for any larger populations may be calculated from the tables by merely adjusting the decimal point nothing is sacrificed by this omission.

Abwehrfermente des thierischen Organismus gegen korper-, blutplasma- und zellfremde Stoffe, ihr Nachweis und ihr diagnostiche Bedeutung zur Prufung der Funktion der einzelnen Organe. Von EMIL ABDERHALDEN, Direktor des Physiologischen Institutes der Universität zu Halle a S. Mit 11 Text-figuren, 1 Tafel. 2. Vermehrte Auflage. Berlin: Julius Springer. 1913. Pp. 199. Price, paper, 5.60 marks; bound, 6.40 marks.

WRITING on June 15th, 1913, the author hopes that the second edition of his work will have as friendly a reception as the first edition. The original title of the work, which was very fully reviewed in THE LANCET of Jan. 4th, 1913, has been changed. The term "Schutzfermente" has been replaced by the title "Abwehrfermente." The illustrations have been increased from 8 to 11, a plate is added to show the arrangement adopted for cooling the polarisation tubes, while the text has been increased from 110 to 199 pages. The literature also has been added to. The text has been thoroughly revised and many additions have been made, but we still could have wished to see the text so set out that the reader could find his way more readily, especially as there is no index. New chapters have been added on the stages in the katabolism of the "Bausteine" of the organism, hermaphroditismus verus, the protective regulations of the animal organism against substances foreign to the blood plasma, preliminary studies on the ferments of normal blood, the formation and sources of protective ferments, anaphylaxy, sero-diagnosis of the functions of organs, the correlation of certain organs. The unity of so-called proteolytic ferments is doubtful. Very full technical descriptions are given of the methods of dialysis adopted and also of the optical methods used by the author. We wish the second edition as rapid a success as its predecessor.

Diseases of the Eye: a Handbook of Ophthalmic Practice for Students and Practitioners. By G. E. DE SCHWEINITZ, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, &c. With 360 illustrations and 7 chromo-lithographic plates. Seventh edition, thoroughly revised. London and Philadelphia: W. B. Saunders Company. Pp. 979. 1913.

THERE is no need for us to reiterate the eulogies with which we have greeted previous editions of this work. It is one of the great standard text-books of the English-speaking medical world, and the new edition serves but to re-establish it more firmly. We think the time has come to alter its *format*: it would be much handier if the pages were rather larger. Its outstanding merit is the abundant reference to all the most valuable contributions to the literature of the subject in recent years, and Dr. de Schweinitz succeeds in incorporating these details without marring the general perspective—no easy task. The new matter comprises paragraphs on Schiötz's tonometer, ophthalmodiaphanoscopy, sporotrichosis, Widmark's conjunctivitis, rosacea keratitis, epithelial dystrophy of the cornea, blue sclerotics, progressive atrophy of the iris layers, exudative retinitis, angiomatosis retinæ, cysts of the retina, blindness from arylarsenates, Siegrist's local anæsthesia, trephining of the sclerotic, Reese's muscle resection operation, and Toti's operation (dacryocystorhinostomia). Vaccine therapy and the indications for the administration of salvarsan receive ample consideration, and special attention has been paid to diseases of septic origin, particularly the more obscure forms of iritis and uveitis. The author's apologies for the shortcomings of his work are sufficiently discounted by the list of editions and reprints which have been found necessary. We can cordially recommend the book as belonging to the small group of the very best text-books on ophthalmology.

LIBRARY TABLE.

Die Fermente und Ihre Wirkungen. Von Professor CARL OPPENHEIMER, Dr. Phil. et Med., Berlin-Grunewald. Band I., vierte völlig umgearbeitete Auflage; und Band II., vierte völlig neubearbeitete Auflage. Nebst einem Sonderkapitel: *Physikalische Chemie der Fermente und Fermentwirkungen.* Von Professor R. O. HERZOG, in Prag. Leipzig: F. C. W. Vogel. 1913. Band I., pp. 485, price, paper 20 marks; bound 21 50 marks. Band II., pp. 1150, price, paper 36 marks, bound 37.50 marks.—The importance of ferments in the great vital processes of the body is now established. They may form, for example, a defence against bacterial invasion and they are concerned in controlling the physiological activities connected with metabolism. The study of ferments is developing very rapidly, and knowledge in regard to these wonderful bodies of the most interesting kind is being accumulated day by day. Biochemistry, indeed, has for its foundations the study of the enzymes and their functions. The ground is well covered in this extensive work upon the subject, the two volumes presenting an exhaustive reference to modern researches. The work is divided into three parts, the first being devoted to the general chemistry and biology of the ferments, the second to the individual ferments, and the third to the chemico-physics of the ferments and the nature of their reaction. This last interesting part is written by Professor R. O. Herzog. The subdivision of these parts into chapters and subsections resolves the enzymes into an excellent system of classification. The references to modern contributions on the subject are very copious, and disclose the fact that no small share of the pioneer work may be allotted to English workers. Prominent among these stand the names of Bayliss and Starling, Vernon, Green, Brown, Morris and Heron, White, Pavy, Plimmer, and O'Sullivan. The real founder of biochemistry, however, was, of course, Pasteur, and a rapid development of his work appeared in the researches of Fischer, Buchner, Kühne, and Chittenden. The history of the enzymes is a most interesting one, and all those who would be conversant with this history, as well as with the medical, chemical, and physical significances of the enzyme in the light of modern research, will consult this work with an obvious gain to their knowledge.

The Further Evolution of Man. By W. HALL CALVERT, M.D. Edin. London: A. C. Fifield. 1913. Pp. 324. Price 5*s.* net.—*The first few chapters of this book are devoted to* an attack upon the Darwinian hypothesis, in so far as that purports to find in natural selection and the struggle for existence a quasi-mechanical basis for the teleological aspect of evolution. In regard to this part of the book Dr. Calvert frankly admits that it is very largely based upon Paulin's work,[1] particularly Chapters III. and V., which deal with the Cannibal Habit in the Male and Malthusianism and the Law of Population. Darwin, with his usual frankness, admitted that he had been unable to ascertain the precise influences by which the assumed tendency of species to increase beyond the means of subsistence is checked, but in default of evidence concluded that the numbers are kept down mainly by starvation and disease. As against this conclusion, which may be called the bedrock tenet of Darwinism, Paulin claimed to have proved the practical universality among all prolific animals of an instinct prompting the male to devour its mate's offspring if it can obtain access to them within a certain number of days after birth. To Dr. Calvert's exposition of Paulin's theory of male cannibalism as a check to undue increase we have referred in a previous issue,[2] in connexion with Mr. Rodier's suggestion for the utilisation of this instinct as a means of exterminating rats. There can be no doubt of the interest and importance of this theory, as the influence of natural selection in the moulding of species by survival value would be reduced almost to vanishing point, once it were proved that the elimination of the "unfit" by starvation or disease is the exception and not the rule in nature. Darwin's views were admittedly suggested by the work of Malthus, whose alleged "law of population" was destructively criticised by Paulin. Dr. Calvert, in a chapter which reproduces the main facts upon which this criticism is based, asserts that Paulin "has proved that population never tends to outrun the means of subsistence; that population recedes when industry and commerce do, and rises again with a period of commercial prosperity. He has shown that war, pestilence, and famine do not limit population; that, in fact, they act at once automatically as an incentive to an increased birth-rate." These points disposed of, Dr. Calvert passes on to the main object of his book—"to ascertain from observed phenomena what is the path which man must follow, and to forecast as nearly as possible his final goal." It is an ambitious programme, and we are bound to say that we are by no means satisfied that it has been adequately carried out. The view taken is that, through the growth of "altruism," due to the permeation of society by the Christian ideal, there has been initiated a progressive amelioration of the general conditions of life, destined to culminate in a universal *régime* of harmony and happiness. It is a very dubious psychology which draws a hard-and-fast line between "egoism" and "altruism," as if they never coincided or had nothing in common. And, in any case, it is at least as tenable that the economic changes applauded by the author are due to the increased egoism of the many who profit by them, as to the growth of altruism among the few who, in a material sense at least, stand to lose thereby.

The Proceedings of the Optical Convention, 1912. Held at South Kensington, June 19th to 26th, 1912. Vol. II. 1912. London: University of London Press. Price 10*s.* net.—For reasons which need not be entered into now ophthalmologists in general hold aloof from the Optical Convention. Without prejudice to the validity of their position, we cannot but regret the detriment which it entails. It cuts them off in large measure from practical acquaintance with the work of such distinguished physicists as Professor R. T. Glazebrook, Professor Silvanus Thompson, Professor Callendar, Professor Poynting, Professor Schuster, and others too numerous to mention. It is the more necessary, therefore, that ophthalmologists should peruse the published accounts of the proceedings of those especially working at the problems of pure optics. There are many in this volume which will well repay their trouble. They will find Professor Silvanus Thompson's presidential address replete with interesting matter. It is an excellent *résumé* of the history of optics to the present day. We would further especially invite their attention to Messrs. C. C. Paterson and B. P. Dudding's contribution on the Visibility of Point Sources of Light, to Messrs. J. S. Dow and V. H. Mackinney's paper on the Measurement of Light and Illumination, to Dr. F. W. Edridge-Green's new Spectral Colour-mixing Apparatus, Mr. Tomlinson's Scotomagraph, Dr. von Rohr's paper on Aspherical Surfaces for Spectacle Lenses (Gullstrand's cataract lenses), and Messrs. A. C. Jolly and A. J. Bull's communication on the Measurement of Colour. These will suffice to show that the work of the physicist should not be neglected, and they will further afford evidence, if such be needed, that the physicist's *ex cathedrâ* statements require the physiologist's criticism.

Die Halluzination: Ihre Entstehung, ihre Ursachen, und ihre Realitat. Von Privatdozent Dr. KURT GOLDSTEIN, in Königsberg. Wiesbaden: J. F. Bergmann. 1913. Pp. 72. Price 2*s.* 3*d.*—Dr. Goldstein has written a useful brochure on the subject of hallucinations. He explains them as due to the abnormal excitability of the particular sense within whose field they occur. Illustrations are given of the various types of hallucination. In this connexion we should have liked to see more investigation of the hallucinations of the muscular sense. The factors concerned in the production of hallucinations are fully dealt with, and there are interesting references to the hallucinations of various figures prominent in the world's history. The paragraphs on the hallucinations of individuals who are mentally normal will repay perusal—a subject on which the Society for Psychical Research made a series of investigations some years ago.

Medical Electricity and Light. By ETTIE SAYER, M.B., B.S. Lond. London: The Scientific Press, Limited. 1913. Pp. 124. Price 3*s.* 6*d.* net.—This is an elementary text-book for nurses, and naturally treats the rather extensive subjects comprised in the title in the shortest and simplest manner. Its main object is to form a guide to nurses so that they may the more intelligently assist the practitioner or specialist for whom they are working. Most forms of treatment and apparatus are described, and the book is fully illustrated, even to the extent of redundancy. It will no doubt be found of real use to those for whom it is intended, but for the professional man it cannot be said to have any value.

Laws (Abstract) and Board Rulings Regulating the Practice of Medicine in the United States and Elsewhere. Twenty-first edition. Chicago: American Medical Association. 1913. Pp. 196. Price 30 cents.—The scope of this extremely useful pamphlet has been increased, so that in addition to Canada and the United States it now contains an abstract of the licensing laws relating to the practice of medicine in all the principal countries in the world. There is also a list of the medical colleges of all countries. It is, of course, most detailed in regard to the conditions for practice in the various States of the United States (each of which has its own regulations, so that a separate licence to practise is necessary for each State). Here it gives under the several States the licensing authority and its *personnel*, the dates when examinations are held, the requirements to accompany an application for licence, the standard required of colleges by the State, exemptions, reciprocity of licence with other States, and the definition of the Act as to what constitutes the practice of medicine. The book will prove invaluable to any medical man contemplating practice in the United States, and is serviceable generally as a book of reference to conditions of medical practice throughout the world. Every care has been taken by the Council of Medical Education of the Association to secure the utmost possible accuracy.

---

[1] No Struggle for Existence; No Natural Selection. By George Paulin. Edinburgh: T. T. Clark. 1908.

[2] THE LANCET, Sept. 6th, 1913, p. 779, "Rat Destruction."

MISCELLANEOUS VOLUMES.

PROMPTITUDE in publishing its Transactions is a great virtue in any conference, and we are glad to welcome the *Transactions of the Fifth Annual Conference* (London: Adlard and Son. 1913. Pp. 222. Price 4*s*. 6*d*., post free 5*s*.) of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis, which was held on August 4th and 5th. Owing to its coincidence with the International Medical Congress, which followed immediately after the British Medical Association, we were unable to devote space to a report of the conference, but undoubtedly the chief interest centred in the discussion on tuberculin treatment, and this discussion was fully reviewed in a leading article in our issue of August 23rd, in which Dr. Hector Mackenzie's general survey of the subject also was published, several other papers having been published in previous issues of THE LANCET. The other papers contained in the Transactions discussed various aspects of coördination of antituberculous measures by Sir Robert Philip, Councillor A. Neal, Dr. A. Ransome, Dr. Hermann Biggs, Dr. W. C. White, Dr. E. Rist, Sir Clifford Allbutt, Professor C. Saugman, Sir William J. Thompson, Dr. E. Coey Bigger, Professor W. H. Thompson, and Lewis Courtauld.——The fact that a little pamphlet, entitled *Preventive Hygiene, an Account of the Brussels International Conferences, 1899 and 1902*, by an ENGLISH MEMBER (London: John Bale, Sons, and Danielsson. 1912. Pp. 36. Price 3*d*.), has reached a fourth edition, shows clearly that many have been anxious to learn the results of these two conferences on the prevention of venereal disease, and as the matter is exciting special attention at the present time we may state that this book presents very clearly one aspect of this important subject. It is not bigoted, and it recognises that the question has many sides, so that it should prove of help to those who wish to know the truth about the methods of the prevention of venereal disease and their results.

A number of reference books claim attention University calendars contain much information of general interest, more especially at the present moment, when reform is in the air and thought is being devoted to educational matters generally, and the purpose and place of examinations in particular.—We have received the *University of London Calendar, 1913–14* (London: Hodder and Stoughton. Price 6*s*. net), which, in addition to the usual information contained in this class of books with regard to curricula, names of members of the various faculties, and so forth, is prefaced by a short history of the University, and includes a coloured map of London showing the constituent colleges and the institutions having teachers recognised by the University.—The *Regulations for External Students* and the *Regulations for Internal Students* (same publishers) are useful and necessary supplements to the University calendar. —*London Matriculation Directory* (London: University Tutorial Press, Limited, price 1*s*. net) gives the questions set at the September examinations, with answers.—*London University Guide* (London: University Correspondence College, published gratis) contains notes on the subjects of the different examinations, with notes on the special subjects, for 1914–15.—*University College (London) Calendar* (London: Taylor and Francis) contains, in addition to the usual information, the examination papers for the session 1912–13.—Other calendars for the new academic year are those of the *University of Durham College of Medicine* (Newcastle-on-Tyne: Andrew Reid and Co., Limited), the *Calendar of the University of Bristol* (to be obtained from the Registrar of the University), and the *Calendar of the National University of Ireland* (also to be obtained from the Registrar). In the last named several changes are announced in the courses and regulations for 1914.—*The Calendar of the Royal College of Surgeons of England* (London: Taylor and Francis, price 1*s*.) has also just been issued. Alterations in the regulations will be found in the annual report of the Council of the College published in THE LANCET of Oct. 18th, p. 1144.

The increasing vigilance of the income-tax authorities is no doubt responsible for the issue of new editions of *Income-Tax Simplified*, by ARTHUR FIELDHOUSE and E. EWART FIELDHOUSE (London: Simpkin, Marshall, and Co., price 1*s*.), and *Guide to the Income-tax*, by F. B. LEEMING (London: Effingham Wilson, price 2*s*. 6*d*.). Both works serve a useful purpose; but we still look for the book—a small one would suffice—specially written to cover the requirements of the average general practitioner.

JOURNALS AND MAGAZINES.

Parasitology. Edited by GEORGE H. F. NUTTALL, F.R.S., and ARTHUR E. SHIPLEY, F.R.S., assisted by EDWARD HINDLE, Ph.D. Vol. VI., No. 3. October, 1913. London: C. F. Clay, Cambridge University Press. Price 10*s*. net; yearly subscription £1 10*s*.—The opening article on the Anatomy of Argas Persicus (Oken, 1818), by L. E. Robinson and J. Davidson, consists of the second part of these authors' exhaustive monograph on the fowl tick. The present part is devoted to an account of the integument, alimentary canal, and the blood vascular, respiratory, and excretory systems, and is profusely illustrated both with diagrams and coloured plates.—The Nuclear Structure and the Sporulation of Agrippina Bona Strickland, by Kenneth R. Lewin, contains an account of the nuclear changes of a gregarine, parasitic in the larva of the rat-flea, Ceratophyllus fasciatus. The various stages in the formation of gametes and the subsequent sporulation are described in detail, and from his account it appears that Agrippina bona does not differ materially from other gregarines in the manner in which the spores are formed.—In an article on Some Peculiar and Probably Specific Bodies in the Erythrocytes in Rinderpest and another Allied Disease, by W. Leonard Braddon, the author describes certain peculiar appearances observed in the blood of animals infected with rinderpest. In order to produce these appearances the blood is mixed with a solution of 1 per cent. potassium citrate and 0·5 per cent. medicinal methylene blue, and of the resulting mixture some specimens are put up under cover-glasses, whilst others are put in watch-glasses exposed to the air but not to light, and arranged as moist chambers. Under these conditions, after periods varying from 6 to 48 hours, peculiar bodies, ranging in shape from dots up to irregular elongate rods projecting from each side of a corpuscle, make their appearance in the red cells of animals infected with rinderpest. These bodies have so far been detected only in the blood of animals suffering from rinderpest or but recently recovered from it; on the other hand, they have never been observed in the blood of normal animals, so that it seems reasonable to assume that they are specifically related to rinderpest, At the end of the paper Sir William Leishman and Professor Minchin add notes, in which they testify to the accuracy of Dr. Braddon's description of the appearances presented in stained preparations of infected blood, but remark that these bodies do not resemble any bacterial or protozoal parasite hitherto known.—Observations on Mammalian Erythrocytes, by J. Charles Johnson, contains the results of a series of examinations of blood-films of both normal and diseased mammals, undertaken in order to determine whether the appearances described by Braddon could be seen in other animals. The blood corpuscles from various sources never presented anything like his description of the alleged parasite of rinderpest, which tends to support Braddon's view that what he describes is specific to that disease.—Tri-radiate Tænia Crassicollis Rud, by S. O. Yoshida, consists of a short note on the prismatic malformation of this species of tape-worm, occurring in Japan.—Seymour Hadwen contributes a most interesting article on Tick Paralysis in Sheep and Man Following Bites of Dermacentor Venustus, accompanied with notes on the biology of the tick. For some time past complaints had been received from a sheep farmer in British Columbia about a form of paralysis affecting his sheep and occurring annually from late February to early April. Dr. Hadwen has investigated this disease experimentally, and finds that it is a form of paralysis occurring in sheep, man, and probably other animals, and is caused by the bites of Dermacentor venustus, one of the common ticks of Western America. The author was able to reproduce the disease by the bites of adult ticks. The resulting paralysis in lambs was found to develop from six to seven days after the ticks had been placed on the animal. "Tick paralysis" is usually of short duration and is benign in character, but occasionally it may persist for long periods and may terminate fatally. The causative agent has not been discovered, and the disease has not been reproduced by inoculation. The most likely hypothesis seems to be that the tick injects a toxin which gives rise to the symptoms, and in this respect it is interesting to note that the ticks usually attach themselves along the backbone of animals. Finally, six cases are mentioned of tick-bites in children being followed by paralysis, in one of which the child died suddenly with symptoms of acute ascending paralysis. After death a large tick was found at the nape of the neck. Photographs are given showing the marked paralysis produced in lambs by the bites of ticks.—Experimental "Tick Paralysis" in the Dog, by Seymour Hadwen and G. H. F. Nuttall, is supplementary to the foregoing paper, and records a positive experiment carried out at the Quick Laboratory, Cambridge, upon a dog experimentally infested with Dermacentor venustus obtained from Canada. A single female tick was placed on this dog and after eight days the animal became paralysed; the symptoms persisted for about five days, after which they subsided and the dog recovered. In addition, guinea-pigs that had been bitten by nymphs and larvæ of Dermacentor venustus were found to die five to seven days later. As the disease is never accompanied by fever and, moreover, cannot be reproduced by inoculations, it seems probable that it is not infective.—The Herter Lecture, III., Piroplasmosis, by George H. F. Nuttall, consists of a useful summary of our knowledge of this important group of diseases, with descriptions of the various parasites and their life-histories, and also methods of treatment and prevention.—Conditions Influencing the Transmission of East Coast Fever, by George H. F. Nuttall and Edward Hindle, comprises a brief account of the effect of certain conditions on the infectivity of ticks infected with Theileria parva. The authors find that infected ticks when feeding on cattle do not produce infection during the first two days, and are still infective after feeding on a rabbit for three days. The partial feeding for two days followed by starvation for 17 days renders them non-infective. Infective ticks were rendered non-infective by exposure to 10° C. for three weeks, but their infectivity was restored by subsequently warming them. The authors suggest that the final development of Theileria parva in the tick, resulting in the latter becoming infective, commences only after the tick has begun to ingest blood.

The Journal of Laryngology, Rhinology, and Otology.—The October issue contains a paper read by Professor E. J. Moure, of Bordeaux, in the Laryngological Section of the recent International Congress of Medicine, on What becomes of Sinuses that have been Operated on? The sinuses referred to are, of course, the accessory sinuses of the nose. Many consider that in order to clear out and eradicate suppuration satisfactorily from a frontal sinus full exposure by destruction of its entire anterior wall, commonly known as Kuhnt's procedure, is indispensable, with the object of bringing the skin into contact with the internal wall of the sinus in such a way as to lead to the complete occlusion of its cavity, whilst Killian has devised an operation going a step further to obtain this apparently indispensable fusion. Professor Moure has long been quite convinced that these different ideas are more theoretical than practical, for he has observed that antra which had been very roomy when first operated upon no longer existed, so to speak, when he had to operate for the second time. The cavities had become filled up with fibrous tissue; even the bony walls had come nearer to one another, so that the sinus, in a measure, had disappeared. This fact—the cicatricial obliteration of the sinuses—at once suggested the question, If sinuses after operation close and fill up, then why perform operations so extensive and disfiguring as those of Kuhnt and Killian? For this reason Professor Moure believes that the Caldwell-Luc operation in the case of the maxillary antrum, and the Ogston-Luc in the case of the frontal sinus, will always be the ideal operations when these suppurating cavities must be dealt with by the external route. This is a matter of capital importance, since it means the reduction to a minimum of deforming and mutilating operations, and lessens the gravity of operative acts which many practitioners hesitate to perform by reason of the unfortunate consequences which they have had at times to deplore

The British Journal of Inebriety.—The October number publishes in full the excellently practical and thoughtful address on Alcohol and the Child-Bearing Woman, delivered by Mrs. Mary Scharlieb, M.D., at the breakfast of the National Temperance League in connexion with the Brighton meeting of the British Medical Association, of which an abstract was given in THE LANCET of August 2nd, p. 293. In an article on Parental Example and Intemperance, the Rev. Professor W. F. Lofthouse summarises the results of an inquiry which he has carried out on this subject by the method of the questionnaire. The replies received appear to have been somewhat indefinite and on some points contradictory, but they showed at all events that the influence of parental example may possibly cause reaction instead of imitation, so that drunkenness in the parents may lead to fanatical teetotalism in the children. An inquiry of this sort if carried out on a wider scale and with more precaution against subjective influences might be of value. In the course of some brief remarks on the Psychological Aspects of the Alcohol Problem, Dr. G. E. Partridge pleads for the abandonment of the naïve ethical judgments which have played so large a part in the discussion of the liquor problem, and outlines a scheme of psychological inquiry into the nature and origin of intoxication motives, considered firstly in relation to the organic constitution; secondly, to environmental conditions; and thirdly, to political, economic, and social activities. The article is suggestive, but necessarily somewhat sketchy.

Revista de la Sociedad Medica Argentina.—Dr. Romulo Chiappori contributes to the current issue of this review an interesting paper on the pathology and inter-relations of the familial systemic degenerations of the nervous system, Friedreich's disease and the syndromes of Strümpell and Marie. The author strongly supports Raymond's view ("Pathologie Nerveuse," 1910) that these affections are not to be regarded as distinct entities, since they are but rarely found pure, patients suffering from any of these affections presenting, in the great majority of cases, both clinically and anatomo-pathologically, symptoms of more than one member of the group. An important feature of the paper is an elaborate and detailed study, histological and macroscopical, copiously illustrated by plates, of the lesions presented in the cerebrum, cerebellum, and upper part of the spinal cord in a case of spasmodic tetraplegia in a child of 4. An excellent bibliography accompanies the paper.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Remuneration of Asylums Medical Officers.

THE Metropolitan Asylums Board recently decided to increase the remuneration of assistant medical officers, giving as one of the reasons that the scale in the London County Council asylums service was higher than that of the Board. At the meeting of the London County Council on Oct 28th, however, the Asylums Committee reported that it had adopted an increased scale of remuneration in respect of these positions. The committee stated that lately it had experienced great difficulty in securing the services of assistant medical officers, and it had become apparent that steps must be taken to improve and render more attractive the positions of the assistant medical staff in the London asylum service. The scale of remuneration for assistant medical officers had not provided hitherto an annual increment for any grade except the first. The fifth and sixth assistants received £170 a year each, the fourth £190 a year, the third £210 a year, and the second £250 a year in each case, with board, lodging, and washing, valued for superannuation purposes at £90 a year. The first assistant received a remuneration of £310 a year, rising by £25 a year to £410, with the same residential emoluments. The amended scale now adopted was as follows:—First assistant medical officer: commencing salary £350, rising by annual increments of £35 a year to £450. Second: £290, rising by annual increments of £10 a year to £330 Third £250, rising by £10 a year to £280. Fourth: £220, rising by £10 a year to £250. Fifth assistant medical officer, and all appointments under: £200, rising by annual increments of £10 to £220. The salaries included board, lodging, and washing in each case. The committee stated that the present expenditure on salaries for assistant medical officers amounted to £11 535 a year, and the amended scale involved an immediate increase of £1620, or just over 14 per cent.

Treatment of Uninsured Persons Suffering from Tuberculosis

When the Council adjourned the report of the Public Health Committee on the treatment of tuberculosis in London [1] had not been reached. The committee submitted a further report as to arrangements for the residential accommodation of uninsured persons. The committee remarked that as the result of legislation passed last session the position of the Metropolitan Asylums Board in relation to the provision of accommodation had materially altered, and, as already reported, the Local Government Board had expressed the opinion that the Council could now deal with the Asylums Board as with any other sanatorium-providing authority. In addition to accommodation which could be provided by the Metropolitan Asylums Board there was no doubt a number of beds at hospitals and sanatoriums available for London patients, and doubtless the existing accommodation, if found to be insufficient, would be augmented by the authorities concerned if they were satisfied that the Council would enter into arrangements with them for its use. The committee invited the Council to express the following opinion:—

> That any comprehensive scheme for dealing with the treatment of tuberculosis in London shall provide that the Council shall make arrangements with the Metropolitan Asylums Board, with hospitals, and with sanatoria for the provision of the residential accommodation required for London uninsured patients suffering from tuberculosis; and that it be referred to the Public Health Committee to consider and report whether adequate provision can be made in this manner without the Council being called upon itself to own and manage institutions.

To this Major LEVITA gave notice of an amendment expressing the opinion that the Council should not act as a financial intermediary between the Local Government Board and either the Insurance Committe [illegible] and should leave the local health [illegible] the Metropolitan Asylums Board and other institution-providing bodies, to deal with the disease of tuberculosis under the same administration as at present dealt efficiently with other diseases.

Future of the Mount Vernon Hospital, Hampstead.

The London Insurance Committee wrote directing attention to the fact that the authorities of the Mount Vernon Hospital at Hampstead wished to dispose of the hospital, and suggesting that the institution should be secured if possible for the treatment of insured persons in London suffering from tuberculosis. The Public Health Committee advised the Council to decline to purchase the institution, and to direct the attention of the Metropolitan Asylums Board to its impending sale.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on Oct. 30th, Sir THOMAS BARLOW, Bart., K.C.V.O., the President, being in the chair.

The PRESIDENT announced that Mr. Frank Caldicott had been elected twenty-first Jenks Scholar.

The following gentlemen having passed the required examination were admitted Members of the College: John Rupert Collins, M.D. Dub. (Cheltenham); Reginald Robert Elworthy, M.B. Lond., L.R.C.P.; George Graham, M.D. Camb., L.R.C.P.; John Athelstan Braxton Hicks, M.D. Lond., L.R.C.P.; and Charles McMoran Wilson, M.D. Lond., L.R.C.P. (Hastings).

Licences to practise physic were granted to 105 gentlemen who had passed the necessary examinations.

The following communications were received: 1. From the Secretary of the Royal College of Surgeons of England, dated August 2nd and Oct. 13th, reporting proceedings of the Council of that College on July 31st and Oct. 9th respectively. 2. From the clerk of the Privy Council, dated Oct. 2nd, with enclosures relating to the International Health Bureau established at Jerusalem, and asking for observations upon the subject. After some discussion it was resolved that the substance of the communication and the correspondence in connexion therewith should be printed and distributed to the Fellows. 3. From Mrs. Edward Walker, of Wimbledon, dated Oct. 7th, offering for the acceptance of the College an original prescription of "Gregory's powder." The gift was accepted with thanks. 4. From Mrs. J. G. Curtis, of Chatham, Mass., U.S.A., dated Oct. 3rd, notifying that she has sent to the College, in accordance with the wish of her late husband, certain papers of the late Dr. Greenhill. The receipt of the papers was acknowledged with thanks.

A report was received from Dr. Aldren Turner upon the Third International Congress of Neurology and Psychiatry held in Ghent. The thanks of the College were given to Dr. Turner for his services. A report, dated Oct. 7th, was received from the Committee of Management. The Committee recommended that the Central London Ophthalmic Hospital should be recognised for the course of clinical instruction in ophthalmic surgery.

Dr. Frederick Taylor was re-elected a member of the Committee of Management.

After some further formal business the PRESIDENT dissolved the Comitia.

In the report of the Comitia held in July last it should have been announced that Dr. W. Rees Thomas, a Member of the College, had passed the additional examination (open to Members only) in Psychological Medicine. This was the first occasion that this examination had been held.

---

[1] THE LANCET, Oct. 25th, p. 1205.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 8, 1913.

Research Work in Insanity and the Study of Curative Treatment of the Insane.

IT we read the signs of the times aright, British psychiatry is beginning to awake from its lethargy. Some 18 months ago we drew attention[1] to the unsatisfactory state of psychiatry in England, its comparative failure to advance notwithstanding the wealth of the material at its disposal, the obvious disadvantages under which the assistant medical officers of average asylums labour, and the absence of schools or clinics, except at one or two places, to attract the overseas visitor or to enlist the foreign graduate as a voluntary worker. But it is impossible for things to remain as they are once the interest of the profession is aroused Those who have devoted and are devoting their best energies to the advancement of scientific psychiatry come in touch with kindred spirits from foreign schools, and their enthusiasm is bound sooner or later to exert a leavening influence on the great mass of latent energy that is to be found in our asylums and similar institutions, waiting for a suitable outlet to develop its powers. British psychiatry can no longer revolve in an eddying backwater while the current of scientific research is flowing strongly past it.

The problem to which we believe the psychiatrical expert is now thoroughly alive is, how to utilise for scientific and curative purposes the immense material at its disposal. An asylum should be as much a centre of research as a hospital: we all know that any self-respecting hospital will labour to keep itself well equipped and to render itself up to date, and the report which we publish this week by Dr. H. OSWALD SMITH, of the Standing Lunacy Committee of the Surrey county council, *on the desirability of organising a research* laboratory at Netherne Asylum, shows that similar efforts are being made by mental institutions. This is indeed a most welcome indication of advance. We are well aware that not a few asylums, county and otherwise, are provided with adequate laboratories and ample material, yet the output of clinical or pathological research is regrettably limited, almost entirely, we venture to think, because the incubus of routine work overwhelms the medical officers Those who have lived and worked in large asylums know how appalling that routine may become. Dr. SMITH, in the case of Netherne Asylum, recommends that research work should be undertaken by a specially appointed officer, either a pathologist or a laboratory physician. The proportion of medical officers who are able to snatch time from their ordinary labours to devote to the prosecution of knowledge for its own sake is a small one, although, no doubt, opportunities are not wanting, but as at present constituted the daily programme of the medical officer of an average asylum is such as to render nugatory the efforts of many, even with the best intention in the world, to follow up lines *of study and investigation which offer themselves to the* observant physician. The proposal, therefore, is to appoint a special officer to work in coöperation with the medical staff, to perform duties more or less analogous to the clinical pathologist of the up-to-date hospital, to associate with the staff in the carrying out of modern lines of treatment rendered necessary by advance in our knowledge of syphilis, of diseases of the ductless glands, and so on. We are less concerned at this moment with the actual adjusting of the relations between such an officer and the residential medical staff; we should think the assistance thus provided and the atmosphere of research thus created are calculated to prove of the greatest value. What elicits our sympathy and our support is the determination of a *responsible board to bring their institution demonstrably* nearer that high level of attainment in curative research reached by the Crichton Royal Institution at Dumfries and by some other asylums in other parts of the country. The report is indicative of a freshening of spirit on the part of asylum authorities and of a healthy restlessness under present limitations which augurs well for the future.

Indeed, we see for a movement subjecting the material of our lunatic asylums to comprehensive and detailed research possibilities for great development. When the lessons learned in the laboratories of the psychiatrist are made available for the use not only of the pathologist but of the general biologist, the biometrician and the eugenist, it is certain that explanations may be forthcoming of problems which at *present* are perturbing the minds of many. Dr. CHARLES MERCIER, in his address upon heredity and inheritance as they concern the physician, delivered before the Society for the Study of Heredity and published in our columns this week, deals with several of those problems in a typically witty, whimsical, and dogmatic manner. With *some of his* criticisms we shall all be in accord, for he is a wise man and a master of his subject, while in other directions his following will not be so large; but a thoroughly scientific inquiry into the pathological condition of the inmates of our asylums cannot fail to clear away differences of opinion, if only by supplying firmer ground upon which to found opposing arguments.

◆

The Extension of Plague.

IT is maintained by many authorities that an epidemic of human plague rarely occurs without an antecedent epizootic among rodents, generally the rat. Similarly it is contended that the endemicity of plague in certain well-defined regions is always associated with an enzootic, and that this occurs often among rodents of the marmot tribe, as, for example, in the tarbagan (arctomys bobac) in Mongolia and other parts of Central Asia, the suslik or spermophile (spermophilus guttatus) in the government of Astrachan in European Russia, and the ground squirrel (citellus beecheyi) in the State of California in North America. In each of these instances just mentioned the flesh of the animal is prized by the natives and eaten in a cooked or uncooked condition. Cases are reported where plague has developed after the ingestion of such flesh; sometimes the hunter or trapper contracts the infection through an abrasion on his hand while skinning the animal. It is, however, probable that the most usual way in which plague is transmitted from the marmot to man is by the agency of the flea as it leaves the dead or dying animal to seek for a fresh host in man, failing another available marmot.

---

[1] THE LANCET, April 6th, 1912.

The history of plague shows that after a pandemic has ravaged the world the disease disappears, often for a long period, emerging again unexpectedly and spreading rapidly from east to west over the globe. Epidemiologists have long regarded China as the home of plague where the virus lies latent between the great pandemics; and history shows plague to be a disease of great antiquity in China. Recently it has been suggested that the conservation of the plague virus in China is due to the tarbagan, the haunts of which are far removed from those of man and the rat; so that long years may elapse before an accidental transference of the infection from the tarbagan to man takes place So long as man keeps away from the tarbagan so long, it is maintained, plague remains latent; but when, as of late years, a demand for the fur of the tarbagan has arisen, Mongols, Buriats, Manchus, and even Cossacks are as a consequence recruited in considerable numbers to hunt and trap the animal on a large scale. It is evident that if plague existed among the tarbagan it is likely under such circumstances to be transferred on some occasions to the trapper in one of the ways indicated above. This is the generally accepted explanation of the origin of the terrible Manchurian epidemic of the winter of 1910–11 On the other hand, Dr. WU LIEN TEH (G. L. TUCK), director of the North Manchurian Plague Prevention Service,[1] contends that the rôle of the tarbagan in the spread of plague is not so important as some experts would have us believe The Russian and Chinese Governments, however, seem to look upon the tarbagan as a source of danger, for during the last two years both Governments have prohibited the systematic hunting or trapping of this animal. The commission appointed by the Russian Government, to investigate the cause of the continued endemicity of plague in the steppes of Astrachan found reasons for suspecting the suslik, or spermophile, of harbouring the disease. Although not yet sanctioned by the Government, plans are under consideration for the wholesale destruction of this marmot in Astrachan. It has been shown by experiment that infection of plague in this animal may be greatly prolonged, especially during the hibernating season. The population of that part of Astrachan where plague is endemic is sparse, and although year after year without exception plague appears among the nomadic tribes of this region, commonly in the pneumonic form, the outbreaks never attain large proportions, probably because the available human material gets exhausted in a short time. Nevertheless, the existence of this plague endemic area on the eastern borders of Europe is not without a certain amount of danger to the Western nations, with which, however, it has but little intercommunication

In California there has existed for some years an enzootic of plague among the hordes of ground squirrels which infest the open plains of the great interior valley as well as the foot-hills and rocky canyons of that region. Sporadic cases of human plague occur from time to time within this area, the last instance being reported so recently as September. Inquiry invariably shows that the person attacked had been shooting, trapping, or otherwise handling ground squirrels on farms where infected animals had previously been discovered. This enzootic of plague has been found so far to extend to 12 of the Californian counties, Contra Costa and Alameda being the worst affected. To Passed Assistant-Surgeon GEORGE W. MCCOY, of the United States Public Health Service, we are indebted for much valuable information respecting plague in the ground squirrel. He has pointed out that in the vicinity of some Californian towns this animal and the rat may be found living in the same burrows. The flea usually present on the ground squirrel feeds readily upon the rat, and the rat flea is equally ready to feed on the ground squirrel. So that it would not be difficult for an infected ground squirrel to infect a rat through the flea and for this rat to carry the disease into a human habitation and communicate the infection to man. This danger is now generally recognised in California, and since 1908 a determined effort has been made to exterminate the ground squirrel, more particularly in the zones around the towns where the danger is regarded as being greatest. This animal, apart from plague, is regarded as a pest, for by its depredations on the crops it causes great losses annually to the farmer. Enzootic plague in California is a menace to the United States, since there is always the possibility of the actual transference of plague infection from these animals to man; and this, in conducing circumstances, might lead to a human epidemic of serious proportions. That the authorities are alive to the danger is evident, for the Californian State Board of Health has sent its secretary to Washington to confer with the Surgeon-General of the Public Health Service, and to invoke the assistance of the Federal Government in carrying out a campaign of "decitellisation," or extermination of the incriminated ground squirrels. All the evidence collected up to the present day points to the conclusion that the persistence of plague from year to year in a locality cannot be attributed to the conservation of the bacillus pestis in a free state outside the living body, but that the persistence is maintained exclusively by the passage of the virus from one living body to another. It may also be inferred that plague was originally a disease peculiar to rodents, and that its extension to the human species was in the first instance accidental.

◆

The Housing Problem in Dublin.

THE leaders of the Labour party in their various speeches in perturbed Dublin during the bitter industrial dispute have said accurate and inaccurate things, shrewd and foolish things, but when any of them laid stress on the housing conditions to which the Dublin workman is subject he was sure of an attentive and sympathetic hearing, for it is well known that the Dublin housing conditions for the labouring classes are too often scandalous. The socio-political circumstances in Dublin have quieted down during the last few days, but the insistence of the labour leaders on the importance of dealing with the housing question, following on the collapse of two tenement houses a few weeks ago, seems to have aroused the public conscience. Something is going to be done; one of the most pressing of municipal and sanitary problems in Ireland is, we hope, going to be tackled. It is at last felt by the community that the housing conditions of Dublin are not merely, as they have been for years past, a danger to the public health, but that they are becoming a menace to the social order.

---

[1] THE LANCET, August 23rd, 1913, p 529.

The facts have, of course, long been known to all who cared to know them. In his official reports Sir CHARLES CAMERON, the medical officer of health of the city, has set them out year by year, when they form the regular text for leading articles in the daily press, where at other times the reflections by medical men and sanitarians upon the matter are regarded apparently as unnecessary jeremiads. Similarly, in his periodic charges to the city grand jury, the Recorder of Dublin, Mr. T. L. O'SHAUGHNESSY, has assigned to the housing conditions of the poor the origin of most of the crime which comes before him. Some of the facts given by Sir CHARLES CAMERON in his last annual report, that for 1912, which has been recently issued, are of such a nature that it is difficult to understand why popular outbursts and subsidence of structures have been necessary before the apathy of the authorities was overcome. The death-rate of the city was 22 per 1000 of the population, and the mortality under 1 year of age was 140 per 1000 births. These figures on their face only convey half their message. Both infant and adult mortality were specially high in the labouring class, so that in less than one-third of the community more than one-half of the deaths of children under 5 years occurred. The houses occupied by the workmen, the parents of these luckless children, are in many respects beautiful ones. They are, almost without exception, Georgian residences formerly occupied by the country gentry and professional families. Many of them are mansions of considerable beauty and size, and they have still the advantage that the rooms are large and lofty, and staircases and landings are spacious. These mansions are decayed to the ruin point, but they still display the virtues of their conception. Other houses are smaller and have little of either light or air, but in both the large and small houses the lettings are for a great part in single-room tenements. There are, in fact, 21,113 families, with a population of about 69,000, living in single-room tenements. That is to say, that over one-fourth of the population of Dublin live in such conditions. In Bristol, a city little larger than Dublin, the proportion of the population living in single-room tenements is only 1·5 per cent., and in Edinburgh, which historically and socially has many resemblances to Dublin, only 5·6 per cent. Needless to say, the death-rates in these cities are much lower than in Dublin. It requires little imagination to conjure up the picture of dirt and disorder to which such over-crowding as occurs in Dublin must conduce. The question of lavatory accommodation is but one of many, but the circumstances set out in this connexion by Sir CHARLES CAMERON may be taken as typical of the horrid whole. It is unusual, it appears, for these houses to contain any sanitary accommodation within the walls—not, perhaps, a matter of great complaint; but the only provision for a houseful of 30 or 40 people—men, women, and children—is too often one water-closet in the yard. It goes without saying that this water-closet, being used by six or eight families, is frequently in a filthy condition, and similar blindness to the ordinary rules of cleanliness can be witnessed in all the domestic circumstances of the Dublin lower classes. It is high time for reform.

It is not to be thought that no attention has been hitherto paid to the housing question in Dublin. Both the Dublin corporation and Lord IVEAGH have spent large sums in clearing some of the worst spaces and erecting healthy and sanitary dwellings. Unfortunately the rents required for these dwellings have put them beyond the reach of the labouring classes, and the tenants are artisans and clerks. Meantime, the clearance of the areas occupied by these new blocks has necessarily increased the congestion of surrounding areas, and the labouring classes, who constitute a large proportion of the working population, find themselves no better off. Under present economic conditions it seems impossible to provide housing for the working-classes at remunerative rents, and the problem is so urgent that improvement in economic conditions cannot be awaited indefinitely. The question is one, therefore, of capital expenditure either by the municipality or the State. The appointment of a Vice-Regal Commission to report as to the best means of procedure has been pressed, but when the Chief Secretary was approached he would not go further than to promise a departmental committee of the Local Government Board. As this body has been fully aware of all the circumstances for years, and has remained inert, little is expected from this proposal by the inhabitants of Dublin.

Annotations.

"Ne quid nimis."

THE PREVALENCE OF FATAL BURNS IN CHILDREN.

EVERY house surgeon and dresser knows how heavy is the toll in infant life, suffering, and deformity occasioned in children through accidents by fire. He also realises that although life may often be saved and suffering alleviated, the resulting disfigurement which in greater or less degree attends nearly all such accidents is permanent. It becomes, therefore, of the first importance that all investigations bearing upon the prevention of such accidents should receive careful consideration. In this connexion attention is called to the article on the mortality of children from burning, by Dr. W. A. Brend, which appears elsewhere in this issue, in which he classifies the deaths in children due to burning between 1906–1911, according to their ages, in boys and girls respectively. Dr. Brend, we think, makes out a good case for the view that the dress of girls is the predominant factor in the great disparity there shown to exist between them and boys as the subjects of such accidents, for this disparity begins to show itself only from the age at which the dress becomes differentiated in the sexes—i.e., about the third year, at which time the ratio progressively decreases in boys, but continues to increase in girls until years of discretion are reached, and even then a decline occurs only very gradually. While the use of inflammable materials is no doubt partly to blame, Dr. Brend lays stress also on the fact that layers of such garments enclosing strata of air between them greatly increase the danger. The tendency to superimpose layers of garments on children is decreasing in these days and giving way to methods of dress more suited to bodily activity, but there are still many thousands of children, female children in particular, who are made into perambulating bundles by ignorant, well-meaning parents. A recognition of the part played by these layers of garments in relation to serious burns will doubtless tend to hasten their much-to-be-desired abolition. A totally different sort of burn is discussed by one of our Scottish correspondents, who points out, also in this week's issue, that a great many of the burns that occur in children in Aberdeen, according to the last report of the medical officer of health, were attributable to the application of poultices to relieve trouble in the chest or abdomen. It seems strange that such lack of ordinary judgment should obtain, but when we recall the fact that even nurses have been known to bathe patients in water that scalded them, one must not be too much surprised at a lack of discrimination in an untrained public. Both forms of injury have this in common—they point to the desirability of a general school training in at least the rudiments of physiology and hygiene.

MOUNTAIN SICKNESS IN THE ANDES.

FEW medical men have such opportunities of studying at first hand the symptoms of mountain sickness as those enjoyed by Dr. T. E. Ravenhill, who contributes a graphic account of this malady to the *Journal of Tropical Medicine and Hygiene* of Oct. 15th. For two years he acted as medical officer to a mining district in the Andes, situated at an altitude of over 15,000 feet above sea level. The railway brings passengers in 42 hours by fast train, in two days and a half if the journey be broken at Calamba, from Antofagasta on the Chilian coast to this high level. Arriving about midday the passenger complains of no symptoms until towards evening; then lassitude is felt, and he wakes up next morning with severe frontal headache, often with vomiting and with a rapid pulse. The tongue is furred and the eyes are dull and heavy, but the temperature is subnormal. A better day follows, and if the patient stays quiet the attack is soon over. To these symptoms, which are known to the natives as "puna," certain serious features may be added. If these are cardiac in type the patient presents the appearance of acute heart failure; the pulse is rapid and the heart-sounds feeble, there is cyanosis with intense dyspnœa, and if this condition is not treated by immediate return to a lower altitude death may follow quickly. It is curious that while perfectly healthy, robust persons may be attacked in this way, those who have cardiac disease are not specially afflicted. In the nervous type of puna delirium may be a prominent symptom, or there may be troublesome and persistent vertigo. In about 20 per cent. there is some epistaxis, but it is rarely profuse; occasionally blood is poured out from other mucous membranes. Puna is more frequently experienced by those who arrive in the mountains during the thundery weather which is common in the earlier part of the year; the best day for arrival is one characterised by clear, dry, cold weather. Those who take alcohol on the journey up suffer worse than those who do not; but travellers who expect to ascend the Andes may be consoled to hear that Dr. Ravenhill found that smoking does not aggravate the symptoms. Muscular work is apt to exaggerate the attack, and it is wise to keep quiet for a day or two after arrival Women seem to suffer less than men, and children less than adults. The aborigines do not suffer from puna as a rule. For the ordinary cases rest in bed with the window well open was sufficient to effect a cure. Aspirin was found to relieve the headache. Certain indigenous herbs, taken in the form of infusions, are supposed by the natives to have a curative action; this, however, Dr. Ravenhill's observations failed to confirm. He found the effect of oxygen inhalations disappointing. It appears that those who live for some time at high levels acquire a certain immunity to these symptoms, which lasts for a short time even if they return to low levels, but a sojourn of any duration quite destroys the beneficial effects of acclimatisation. On the other hand, the man who lives at the high levels feels fatigue more readily than one who has been living at ordinary altitudes and comes up thence to the mountains. The quicker the upward journey, the more intense the symptoms; and in certain valleys and other districts persons are inexplicably more liable to puna. A rapid descent to the lower altitudes is as a rule attended by little discomfort beyond headache and tinnitus. In conclusion, Dr. Ravenhill gives some interesting figures to show how rapidly the number of red blood corpuscles increases on arrival at high altitudes; in his own case they passed eight millions per cubic millimetre on the fifth day, and remained there or thereabouts indefinitely, and observations on other persons showed that this was an average experience.

VAGITUS UTERINUS.

VAGITUS uterinus is a very rare occurrence. Indeed, the reported cases have been received with considerable scepticism, and the arguments have been advanced that the sound heard was produced outside the uterine cavity and that air cannot gain access in sufficient quantity for respiration. In the *New York Medical Journal* of Oct. 11th Dr. J. H. Telfair has reported the following case which is unusually convincing, as the cries were heard by four practitioners. A woman, aged 24 years, was in her second labour at the Lying-in Hospital, New York. The first labour had been easy and the pelvic measurements were normal. After 36 hours she was exhausted and the cervix had dilated to the size of a silver dollar. As the fœtal heart was becoming weak and irregular it was decided to interfere. The cervix was soft and was manually dilated to the full extent in 20 minutes. The head was in the right occipito-posterior position and unengaged and the membranes were unruptured. Internal podalic version was performed, the membranes rupturing when version was half completed—i.e., when the long axis of the fœtus was at right angles to the uterus. At this time Dr. Telfair's right arm was in the uterus up to the elbow. The left leg was brought down to the vulva. He had just grasped the foot loosely preparatory to traction when his assistant flicked the sole with his finger. The plantar reflex was excited and the child gave a prolonged cry followed by two short, sharp cries. The cries sounded exactly as if the child were completely enveloped in a heavy blanket. Hurried extraction was performed, occupying less than a minute. The child breathed and cried normally without stimulation and showed no signs of having inspired more than the ordinary amount of mucus. It weighed 3560 grammes. Owing to the rapid delivery the cervix sustained severe bilateral laceration, which was repaired at once. The puerperium was uneventful. Three other members of the hospital staff (an attending physician and two of the house staff) were present and heard the cries distinctly. Dr. Telfair asks the question, Could a man of any experience mistake any other sound for the cry of a babe? In the criticism of the recorded cases the sound has been attributed to a vibrating fold of membrane in the vagina, to the passage of gas per rectum, intestinal rumbling, and so on. For the production of vagitus uterinus two things are necessary: ruptured membranes and the presence of air in the uterus. In introducing the hands or instruments into the uterus it is difficult to exclude air. Air having once gained access, what is to prevent it filling all the interstices between the fœtus and the uterine wall? In normal labour after rupture of the membranes the head acts as a plug, and sufficient liquor amnii to fill the interstices between the fœtus and the uterine wall remains. During operative delivery the whole of the liquor amnii may drain away, and the interstices then become filled with air. The hand and arm of the accoucheur in the uterus, by further separating the uterine wall from the fœtus, enlarge the space not filled by the fœtus. Given air in the uterus one inspiration would be sufficient for a cry. There are two theories as to the cause of the commencement of normal respiration—the stimulus of air on the skin and the accumulation of carbonic acid in the blood in consequence of separation of the placenta. In the case recorded above stimulation of the skin seemed to be the cause, for the *uterus did not appear to be sufficiently retracted to* cause separation of the placenta. Moreover, the success of cutaneous stimulation of the newly born child when cessation of the placental circulation has failed is well known. Of 44 reported cases of vagitus uterinus more than half were operative deliveries, 11 being forceps, 15 versions, and one replacement of arm and cord. The fœtal mortality was 10 per cent. Dr. Telfair holds that once vagitus uterinus is heard the only hope of saving the child lies in rapid extraction, even at the expense of maternal lacerations. But unless the stimulus to inspiration be separation of the placenta, which he argues is not necessary, it is difficult to see why the child should be regarded as in so much danger.

WILSON AND WILSON v. MICHIE.

IN a probate action arising out of the will of Julia Beale Clout, a widow 49 years of age, a brother and sister of the deceased claimed to have the probate of her will and of a codicil, both made in 1912, revoked. By these the testatrix gave the whole of her property to Mr. J. Michie, who had been her medical attendant during the latter years of her life. By previous wills her relatives would have benefited. *The plaintiffs alleged that the* will and codicil had been made under the undue influence of the defendant, and also that at the time the deceased was of unsound mind and wanting in testamentary capacity. The solicitor who prepared the will and codicil in question, under which Mr. Michie was sole executor, gave evidence to the effect that he took his instructions from the testatrix in her own house, and that the defendant was not present either when the instructions were given or when the will and codicil were signed. He also stated that the testatrix was at the time of a sound disposing mind. This evidence, so far as it concerned the mental capacity of the deceased, and the absence of any appearance of influence exerted by the defendant, was corroborated by a servant and a nurse. The defendant also went into the witness box and gave a full account of his relations with the deceased, which he stated, were those *of a medical man towards his patient.* There was evidence given of dislike evinced by the deceased towards her relatives. After the defendant's case on behalf [illegible] had been concluded the plaintiffs gave [illegible] The judge [illegible] box, found that the will and codicil had been duly executed, that the deceased knew and approved of their contents, and that they had not been obtained by *the undue influence of the* defendant. Judgment was accordingly *entered for the* defendant with costs, Mr. Justice Bargrave Deane declining to allow costs out of the estate in the case of charges of using undue influence which had broken down.

ENTEROGENOUS MESENTERIC CYSTS.

A DEVELOPMENTAL anomaly which has received attention only in recent years is enterogenous mesenteric cysts. Their literature is almost entirely foreign; about 100 papers have been published since 1900. Enterogenous mesenteric cysts are of considerable surgical importance, but have probably never been diagnosed before operation or necropsy, and their mortality is about 35 per cent. In the *Johns Hopkins Hospital Bulletin* for October Dr. R. T. Miller has reported the following case. A female child, aged 4 days, was admitted into St. Francis Hospital, Pittsburgh, on Sept. 28th, 1912. She was the last of 13 children, all of whom, as well as the parents, were alive and well. Labour was normal. The child vomited everything taken, and the vomit was greenish-black. The bowels never acted, and there was no stain on the napkin. On examination she looked very ill. At intervals she cried in a thin weak voice as though suffering from paroxysms of pain. There was marked cyanosis of the face and hands. The skin was dry and wrinkled, especially over the extremities. The expression was pinched and drawn, and the limbs were little moved. The abdomen was not distended, and there was no visible peristalsis. Palpation caused the child to cry and was unsatisfactory. No mass could be felt or muscular spasm recognised. The abdomen generally was tympanitic, and there was no dulness in the flanks. The little finger could be inserted its full length *into the rectum without encountering any obstruction.* The rectal temperature was 97° F. Intestinal obstruction due to some unknown cause was diagnosed. Under chloroform a right rectus incision was made. On opening the peritoneum both dilated and collapsed cyanotic loops of small intestine were seen. In the right flank just below the level of the umbilicus a freely movable mass was found. This proved to be an oval intramesenteric tumour, about 4 cm. in its greatest diameter, and quite firm. Over the dome of the mass coursed a loop of small intestine which was flattened into a thin band by pressure. There was a volvulus of the mass and affected sector of the bowel of more than 180°, causing complete intestinal obstruction. The afferent bowel was greatly dilated and the efferent bowel collapsed. After reduction of the volvulus a circumferential area of pressure necrosis with a minute perforation was found. The patient's condition demanded haste, but a rapid enterostomy was not feasible as the obstruction was high in the jejunum. Resection and lateral anastomosis were hurriedly performed and the abdomen closed. Death occurred five hours after the operation. The tissue removed consisted of a loop of bowel 8 cm. long, within the mesentery of which was an egg-shaped mass measuring 4 by 3 cm. This was a cyst the wall of which was in part directly continuous with that of the jejunum. The cyst was lined with a *layer of columnar* epithelial cells bearing villi and resting upon a layer analogous to the submucosa, outside which were transverse and longitudinal layers of smooth muscular fibres. The structure of the cyst was thus exactly similar to that of the bowel, from which it had evidently been formed by sequestration during embryonic life. The adjacent portion of bowel was so stretched that its lumen was represented by a mere slit. In 1907 Niosi gave what appears to be the best classification of mesenteric cysts of embryonic origin, which is as follows. 1. Cysts of intestinal origin—(*a*) by sequestration from the bowel during development; and (*b*) from Meckel's diverticulum. 2. Dermoid cysts. 3. Cysts arising from retroperitoneal organs (germinal epithelium, ovary, Wolffian body, Müllerian duct). The idea that a portion of an embryonic organ may become sequestrated and continue to develop, usually in an anomalous manner, is familiar. The lumen of the cyst constantly but slowly enlarges in consequence of retention of its own secretion. The actual process of sequestration from the developing gut was not observed until 1908, when Lewis and Thyng described the "regular occurrence of intestinal diverticula in embryos of the pig, rabbit, and man." These diverticula consist of downgrowths of the intestinal epithelium which may terminate in the muscular coat of the bowel or may extend quite through the bowel wall to form knob-like projections. They usually degenerate and disappear, but if one persists it may give rise to a mesenteric cyst. The surgical importance of mesenteric cysts lies in their liability to give rise to acute intestinal obstruction. The best treatment is enucleation when it can be done without seriously injuring or opening the bowel.

THE REGISTRATION OF PLUMBERS.

From a strictly medical standpoint the plumber is well deserving the attention he has received within recent times, but more is required to safeguard the public against possible evils likely to arise from incompetence or carelessness on the part of men engaged in plumber's work. Mr. W. D. Caroe, R.I.B.A., Master of the Worshipful Company of Plumbers, speaking at the Royal Technical College, Glasgow, impressed upon his audience that merely registering the men was not sufficient. Responsibility should be fixed on each man for the work he has executed, and this could only be done by every individual marking his work with his registered number. Mr. Caroe thought that every skilful man would be proud to identify himself with his work. The employment of registered plumbers would then stand as a guarantee of efficiency. It unfortunately happens that a great number, perhaps a majority, of those engaged in the plumbing trade are at present not registered, and have therefore no certificate to offer to the public in proof of their capacity for discharging efficiently and conscientiously the important work in which they are engaged, though doubtless many would experience no difficulty in passing the required tests. Mr. Caroe pointed out that the complexity of plumbers' work in modern times had so increased that it was more than a handicraft—he evidently considered it to be almost a branch of practical scientific work, and much can be said for the view. He urged, therefore, on educational authorities the need of providing technical instruction in harmony with the registration system, while the system of apprenticeship should be encouraged. To the men he pointed out that they should claim the privilege of their craft and qualify for registration, setting aside petty disputes and concentrating their attention on the lifting of a responsible handicraft to its merited position. All this we endorse. Unfortunately the bulk of the public, until some catastrophe happens through his carelessness or incompetence, regard the plumber and his work with little interest. The blame for any mischance which should rest upon their own lazy shoulders is shifted anywhere else. Properly qualified men can always be obtained for plumbing work if sufficient interest is exhibited by the employer in the way in which plans are executed, and registration is the obvious method by which a good supply of men can be kept up to the standard. If only this was kept in view every capable plumber would get himself registered, in order to be distinguished from the mass, some of whom may be ignorant or incompetent workmen. Under certain conditions the Plumbers' Company guarantee the work of their registered men. At present all registered men carry a card with their number on the register. It has been suggested that it would be desirable if each man wore a badge, the absence of which would put the public on their guard. This is the day of badges, and only the demand for registered plumbers will create the supply. The suggestion has practical force.

HEALTH OF THE POST OFFICE STAFF.

In his annual report the P [illegible] s that the health of the staff has a [illegible] .. The average sick-rate of the established staff during the year ended Dec. 31st, 1912, was 7·5 days for men and 10 9 days for women, and of the unestablished staff 4·6 days for men and 4·9 days for women. Seventy-five deaths and 111 retirements were due to diseases of tuberculous origin. The deaths recorded through the year showed an annual death-rate of 3·4 per 1000 for men and 1·3 for women on the established staff.

THE WILLIAM H. WELCH ENDOWMENT FOR CLINICAL RESEARCH.

The magnificent gift by the General Education Board, founded by Mr. John D. Rockefeller, of $1,500,000, to provide professorial salaries in connexion with the Johns Hopkins Hospital and Medical School at Baltimore, marks an era in medical education. A professor of medicine, a professor of surgery, and a professor of pædiatrics are to be provided by the new endowment with salaries sufficiently high to make them independent of private work, and with a staff of assistants and laboratories, and are to devote themselves to scientific research in their respective departments. Dr. William Stewart Halsted, the present holder of the chair of surgery, has already accepted his chair under the new conditions. In view of the recent report upon the affairs of the University of London, the institution of these salaried professorships is of the first interest.

THE DIFFICULTIES OF DIAGNOSIS IN ANOMALOUS PLAGUE.

In another part of our present issue we publish a very interesting and instructive communication by Dr. W. J. Tulloch, of Newcastle-on-Tyne, on the bacteriological diagnosis of plague, and in this he draws attention to the many difficulties which exist in recognising cases of plague which may arrive on our shores on healthy ships from foreign ports not known to be infected. Dr. Tulloch urges the examination by blood culture as a method to be adopted in all doubtful cases, and if used as a routine procedure in the indefinite febrile illnesses which occur on board ships it would, he contends, be found a valuable aid to diagnosis. The particular instance so carefully described by Dr. Tulloch occurred on a ship in the Tyne. The strain of the plague infection appears to have been peculiar, since two other cases of illness had previously occurred on the same vessel while it was lying in the Elbe and just before it sailed for the Tyne. The first case was diagnosed as influenza, but proved fatal on the third day; the second case had symptoms suggestive of enteric fever, the illness lasting 23 days before it terminated fatally. Post-mortem examination with bacteriological investigation of material ultimately established a diagnosis of plague in each case. The vessel in question with a cargo of grain, which is known to attract rats to the ship while it is loading, sailed for Hamburg from the Argentine port of Rosario, which has long been under suspicion in Europe of concealing the prevalence of plague in man and the rat in that place. The ship carried four apprentices, who occupied a cabin at the stern of the vessel far removed from the quarters of the crew. The lads had a pet rabbit which was infested by fleas; it died while the ship was in the Elbe. It is conjectured that infected rats came on board at Rosario with the cargo; and that towards the end of the voyage the rabbit contracted the disease from the rats and conveyed it to three out of the four boys who were accustomed to play daily with their infected pet. The strain of infection, though peculiar in its manifestations, was nevertheless of a virulent kind, as all three apprentices died from it.

THE LONDON COUNTY COUNCIL AND THE TREATMENT OF TUBERCULOSIS.

THE London County Council, which has now apparently accepted the view of the Local Government Board that it, and it alone, should constitute the tuberculosis authority for the metropolis, is finding the preparation of a comprehensive scheme a task of much difficulty. For over a year the Public Health Committee of the Council has been engaged upon the problem of sanatorium benefit in London, and, as reported in our columns from time to time, the Council has had before it various recommendations. But the matter progresses slowly amidst the sharp differences of opinion, upon principle as well as detail, which are revealed in debate. London still lacks, even in outline, a coördinated scheme for dealing with its estimated 60,000 tuberculous inhabitants. At its last meeting on Nov. 4th the London County Council discussed the financial basis of that part of the Public Health Committee's report which concerns dispensary treatment of uninsured persons, and eventually some measure of agreement was reached. But the formulation and the carrying into early effect of a complete tuberculosis scheme for the metropolis are such pressing affairs that we may well ask all political parties within the Council to eschew recriminations and keep strictly to the business in hand.

THE IODINE CONTENT OF FISH THYROIDS.

THE observation that a fish diet increased the iodine content of a dog's thyroid was made some time ago. The constant presence of iodine in sea water has suggested that the thyroid of salt-water fishes might contain a relatively large amount of iodine. If iodine is present in sea water as suggested by Gautier in organic combination it is probable that the iodo-organic compound is capable of assimilation and transmission. It now appears from an interesting note upon this subject by Mr Alexander T. Cameron, published in the October number of the *Biochemical Journal*, that definite evidence has been obtained that unusually large amounts of iodine are constantly present in some species, a finding which lends some support to the view that the iodine content of the thyroid is a function of iodine in the diet. In the specimens of fishes selected for analysis the thyroid of the *raia clavata* was found to contain amounts which were not extraordinary compared with that found in the thyroid of the mammals, but the thyroid of scyllium canicula contained more, and in one case much more, iodine than any thyroid previously reported upon. Thus, accepting the following figures for the dog as 0·692 per cent. on dried gland, 0·588 per cent. for the human gland, 0·531 per cent. for the gland of the pig, 0·53 per cent. for the gland of the sheep, and 0·477 for the gland of the ox, the fish thyroid referred to contained as much as 1·160 per cent. of iodine. This is, of course, a very remarkable amount, and further investigations in this direction will be looked forward to with interest. The research, so far, suggests that fish thyroid would be a valuable therapeutic agent, and would appear to add strength to the view that the iodine value of the diet plays a considerable rôle in determining that of the gland.

SIR RICKMAN GODLEE'S VISIT TO THE UNITED STATES AND CANADA.

Sir Rickman Godlee, President of the Royal College of Surgeons of England, accompanied by Lady Godlee, left at the end of October for Chicago, where he is to give an address at the first congregation of the American College of Surgeons and admit the Fellows of the new college. The address will take the form of a historical sketch of the English College of Surgeons, and will detail the circumstances in which the order of Fellows came into being. Sir Rickman Godlee hopes to avail himself of an invitation to visit Toronto, where a number of Fellows and Members of the English College are resident.

THE GENERAL MEDICAL COUNCIL.

THE next session of the General Council of Medical Education and Registration is announced to begin on Tuesday, Nov. 25th. The illness of the President, Sir Donald MacAlister, has now taken a favourable turn, but he will be unable to attend the Council. A chairman will be elected for the forthcoming session, a precedent for which proceeding occurred during the illness of Sir Richard Quain in the autumn of 1897. There will be no change in the plans for the forthcoming session.

Sir Thomas Oliver will deliver a course of six lectures on "Industrial Hygiene" at the Royal Institute of Public Health, the first two of which will be given on Wednesday and Thursday, Nov. 12th and 13th, at 5 P.M.

THE King has approved the appointment of Surgeon-General Arthur Thomas Sloggett, Director of Medical Services in India, to the post of Director-General of the Army Medical Service, in succession to Surgeon-General Sir W. Launcelot Gubbins, whose term of office will shortly expire.

A SPECIAL meeting of the Representative Body of the British Medical Association has been summoned for Thursday, Dec 4th, and if necessary Friday, Dec 5th, at the Connaught Rooms, Great Queen-street, London, W.C. The business before the meeting includes the proposal to raise the annual subscription to 2 guineas; the alternative schemes of the State Sickness Insurance Committee and the National Insurance Act Committee for the establishment of a special fund for professional organisation; and the Council's report on various matters relating to the National Insurance Act.

THE King, acting on the recommendation of the Home Secretary, has appointed the following to be paid Commissioners under the Mental Deficiency Act, 1913: Sir William Byrne, Dr. Arthur Rotherham (medical superintendent of Darenth Asylum), and Miss Mary Dendy. The four unpaid Commissioners have yet to be appointed. The new Board of Control under the Act consists of Sir William Byrne (chairman), Dr. Rotherham, Miss Dendy, and Mr. B. T. Hodgson (secretary to the Board of Commissioners in Lunacy), together with Dr. C. Hubert Bond, Dr. Frederick Needham, Dr. E. M. Cooke, Dr. Sidney Coupland, Mr. L. L. Shadwell, Mr. A. H. Trevor, and Mr. S. J. F. Macleod, K.C. (Commissioners in Lunacy).

RESEARCH WORK IN INSANITY AND THE STUDY OF CURATIVE TREATMENT OF THE INSANE.[1]

BY H. OSWALD SMITH, M.B., CH.B. EDIN.,

MEMBER OF THE STANDING LUNACY COMMITTEE OF THE SURREY COUNTY COUNCIL; MEMBER OF THE NETHERNE VISITING LUNACY COMMITTEE, CURATIVE RESEARCH, AND MENTAL DEFICIENCY COMMITTEES.

A Report to Establish and Organise a Research Laboratory at Netherne Asylum.

THIS report is based on methods adopted by several of the large asylums, at the heads of which are medical men who have advanced psychiatry to a much more hopeful position, and whose efforts are still being maintained along these channels of research whereby new methods of treatment are evolved for the benefit of the mentally afflicted.

An asylum ought not to be merely a place where patients are well cared for and housed, but must have a definite plan so that research work is undertaken by a specially appointed officer who is enthusiastic about his work and efficient in the present-day technique of research work in psychiatry. He should have the proper facilities in a well-equipped laboratory for laboratory diagnosis and study. There must, however, be cooperation between this officer and the resident staff in the work. The primary duty of the resident staff is —(1) the proper examination, (2) treatment, and (3) care of the patients. This work provides infinite lines for study and research for the medical staff, provided always that their primary duties do not take up their whole time. It is well known that certain men who are interested in research work will make time for such extra duties; thus they keep abreast of medical progress and form their own judgment as to the permanent value of the latest advances and ideas.

There are many lines of a clinical and therapeutical nature that can be most appropriately followed out by the ordinary staff. At the same time it is of the greatest advantage to county asylums, such as Netherne, that a fairly equipped laboratory should be regarded as essential. If the ordinary medical staff find that their time is so fully taken up with the ordinary work in the wards that they have not time or that they have not the necessary technical training to do laboratory work—as to the amount of medical work in an asylum the annual admission rate gives a fair indication of the amount of work to be undertaken—a pathologist should be provided at a salary of not less than £250 a year to begin with, in order to get a really good and efficient man, because the ultimate research work would rest largely in his hands. If the assistant medical officers have time to follow up a clinical and therapeutical research, then such an appointment would bear good results, but if the medical staff have not the necessary time, then instead of a pathologist the appointment of a laboratory physician might be made at an initial salary of £250 a year.

This physician could have the laboratory fitted up according to his special requirements, and such sum as £250 as a preliminary outlay would be sufficient. It is only after years of time, thought, and expenditure of money that curative research has reached the high-water mark obtained in such asylums as the Lancashire County Asylum, at Prestwich, the Crichton Royal Institution, and the Edinburgh Royal Asylum. The knowledge of curative research is added to slowly, but if such a scheme as the above is adopted at Netherne the committee will have the benefit of the research work of these asylums and the practical results. When Netherne earns such a report from the Commissioners in Lunacy as the Crichton Royal Institution did for 1912, then, and not till then, shall we be able to say that the patients at Netherne are receiving the most appropriate treatment. If the total expenditure on research work be divided by the average amount of patients under treatment a year it will be found that the general cost per caput per annum for the purposes of laboratory diagnosis, study, and research is not a fraction of the cost of each patient's keep, and such expenditure would be well worth it.

Estimate (apart from cost of building) of initial expenditure for the
urative research work at Netherne.
of £250 a year, with residence; or at a salary
side.
A further sum of £250 for initial expenditure in fitting up a
the coöperation of the resident medica
nd therapeutical treatment.
meanwhile the appointment of a—

Laboratory physician at an initial salary of £250 a year, with residence; or £300 a year outside.

A sum or £250 for initial expenditure in fitting up a laboratory.

Forms of application for the above post, whichever is decided upon, can be subsequently drawn up so as to get the best candidates.

Organotherapy.

The second part of this report deals with organotherapy and the open-air treatment of the active insane by rest in bed. The committee must look to the resident medical staff to carry out this part of the work. In psychiatry and neurology great advances have been made, and these are due to the whole-hearted efforts of men who have ever kept the flag of research flying. There opens out the vista of organotherapy, and by this is meant the employment of certain glandular extracts in the treatment of insanity. Thyroid extract, cerebral extract, mammary, pancreatic, ovarian, pituitary and orchitic extracts, these are some which have been used and experimented with by psychiatrists. It is known that causes of cretinism can be combated by the use of thyroid, and Brown-Séquard maintained that he had "rejuvenated" himself by orchitic extract. Myxœdema, due to the absence of the thyroid gland, can be cured by the administration of thyroid extract. Cerebral extract is found to promote the appetite, and is a good tonic to the general nervous system. These are some examples of the research work placed at the disposal of humanity and obtained by means of work in the laboratory. The committee should expect coöperative research to be based on these lines, which should also embrace the bacteriological examination of the blood and cerebro-spinal fluid, the conditions of which have an important bearing on general paralysis of the insane. The use of vaccines and antisera would have to be investigated.

Administrative duties have become so heavy that it is impossible in many cases for the medical superintendent to give much attention to clinical work, and so we must expect the assistant medical officers who have adopted lunacy service as a specialty to be properly trained in up-to-date knowledge of the treatment of the insane. Post-graduate courses are provided in connexion with most of the universities.

Open-air Treatment by Rest in Bed.

And finally there must be placed on record an estimate of a form of treatment of the insane from which there is expected brilliant results. It is the open-air treatment of the active insane by rest in bed. This treatment can be carried out by the staff without undue strain on their time and little additional expenditure of money. It has been carried out with great success at Ayr Asylum with a resulting increase in the recovery rate Verandahs are used on the male and female sides. Separate beds with wooden partitions are placed on these verandahs. (Details of the scheme can be supplied.)

What are the effects of rest in bed in the open air in the case of newly admitted and actively insane patients, and wherein do the effects of outdoor rest in bed differ from those of outdoor exercise and indoor rest? First and foremost, there is a rapid subsidence of the active mental and nervous symptoms, there is a rapid amelioration of mania, melancholia, delirium, vivid hallucinatory and delusional manifestations, of restlessness and excitement of all kinds and insomnia. The general effect is that the large majority of newly admitted patients show distinct improvement of various morbid mental states, become less restless, more manageable, and more contented, and regain their sleep with greater rapidity than with any other known method. Secondly, there is a rapid improvement in the physical condition, a noticeable improvement in the condition of the skin, the appetite improves, and the majority readily take their food and do not require to be spoon-fed as is usual with new patients; a distinct improvement in the state of the tongue and gastric digestion if previously impaired. Hypnotics, sedatives, and laxatives can under this treatment be dispensed with. The increase in the body weight is 5 lb., 6lb., or 7 lb. during the first two or three weeks on simple diet, consisting largely of milk and milk-puddings.

---

[1] Being a report to establish and organise a research laboratory at Netherne Asylum, with remarks upon the open-air treatment of the insane and organic therapy treatment. The report was adopted by the Standing Lunacy Committee of the Surrey county council on July 7th, 1913.

Similar treatment can be adopted in the cases of all residents of shorter or longer standing, exhibiting relapses or phases of active insanity, including the most difficult and dangerous cases in the asylum. The wooden partitions already alluded to add the valuable feature of isolation to the treatment. The recovery rate is remarkably influenced by this treatment. From the description of the open-air treatment of the insane it will be at once seen that the combination of rest in bed with open-air treatment secures the natural rest to the nervous system and gives the patients in their initial treatment a good chance of recovery; the cost in mere money would be very little in comparison to the benefits. It is a pleasant remedy, both to those who receive the treatment and those who administer it. In placing these points before you, I wi [illegible] I have received from many c [illegible] have willingly placed their [illegible] benefit of the committee. I [illegible] many of the special papers p [illegible] The length of the report is owing to the difficulties of the subject which has been *too* inadequately handled by me.

The Recovery Rate and the Cost of the Schemes.

The recovery rate for 1912 on all admissions into the Crichton Royal Institute was 35·5 per cent.; the Edinburgh Royal Asylum 36·0 per cent. In both these institutions research work is diligently carried on. The recovery rate on all admissions into Netherne Asylum for 1909 to 1912 was 12·0 per cent; Brookwood Asylum for 45½ years, 24·6 per cent. In future the annual recovery rate should be placed on record, so that a just and fair comparative result may be available.

It is therefore necessary to deal with curative research at Netherne Asylum from the practical point of view so far as cost is concerned. Dr. S. N. Crowther, senior medical officer of Netherne, has worked out the cost of a scheme which includes buildings, fittings, salaries, and upkeep. This scheme embraces the cost of open-air treatment of the insane by rest in bed and the proper grading of the insane.

Summary of annual cost per head per week.—(1) Curative research, 2·51*d.*; (2) open air treatment, 1·35*d.*; (3) grading of patients, 4·03*d* —[illegible] 0; [illegible]

The Grading of Patients.

The attention to the proper grading of patients in all asylums is called for. Asylum patients may be divided into two main classes—(1) curable and (2) incurable; and while for those of the first class every means known to science should be used to facilitate recovery, the treatment of the second class is not so important, and the present method of grading is on the whole satisfactory. It is mainly the extra cost which has hitherto deterred the asylum authorities from proper grading of patients. It was usual to distribute a certain number of noisy and excited patients among those who were miserable and depressed, with the hope that an interaction might take place to the mutual benefit of the patients concerned. Such [illegible] background, and it is only [illegible] treatment, stimulated by [illegible] take the long-awaited step forward.

I wish to thank Dr. Crowther for his help and valuable suggestions in the preparation of my paper.

ROYAL ARMY MEDICAL COLLEGE.

ON Oct. 29th a distribution of prizes by Surgeon-General Sir HAVELOCK CHARLES, G.C.V.O., took place at the Royal Army Medical College. A large company assembled to do honour to the occasion, among them being Surgeon-Generals W. Donovan, Sir David Bruce, G. J. H. Evatt, H. R. Whitehead, W. H. Macnamara, Sir Francis Trevor, and Sir Charles Cuffe, A. W. May (Director-General of the Medical D [illegible] Barker, and Dr. F. W. Mott.

Surgeon-General W. BABTIE, V.C., C.B., C.M.G., Deputy Director-General, opened the proceedings by calling upon the Commandant to read his report.

Colonel BRUCE M. SKINNER, M.V.O. (Commandant), reviewed the session, the 106th of the junior class of the College, being also the twenty-third held in London. After referring to the Seventeenth International Congress of Medicine, the Naval and Military Section of which held its meetings at the College, he said there had been some changes in the staff. While regretting the completion of tenure of their appointments, they of the College wished God-speed to Major W. S. Harrison, lately professor of tropical medicine, and to Major J. C. Kennedy, assistant professor of pathology, with the hope that their talents so long devoted to this College might find fields fruitful of discovery awaiting the application of their highly trained energies. On the other hand, they welcomed their successors, Lieutenant-Colonel O. L. Robinson in the chair of tropical medicine, and Major S. L. Cummins as assistant professor of pathology. With regard to the class now being closed he reminded those present that they were fully qualified doctors before passing into the College, where they had been instructed in matters relating especially to the preservation of health and physical well-being of the soldier. He had nothing but praise for the young officers who composed this class, for they had been most assiduous and attentive, while those who had gained prizes had done remarkably well, and in two cases brilliantly, for instance, the winner of the Fayrer and the Marshall Webb medals had gained over 90 per cent. of marks in those competitions. He then read the names of those who had gained prizes, as well as those who came second, as follows:—

	Marks.
1st. The Herbert Prize (highest total of marks): Lieutenant R. B. Price, R.A.M.C.	565/700
Proxime accessit: Lieutenant H. C. D. Rankin, R.A.M.C....	536/700
Hygiene.	
1st. Parkes Memorial. [illegible]	153/200
Proxime accessit: [illegible]	151/200
2nd. De Chaumont: L[illegible]	144/200
Proxime accessit: [illegible]	142/200
Pathology.	
1st. Fayrer Prize: [illegible]	181/200
Proxime accessi[illegible]	160/200
2nd. Tulloch Memo[illegible]	168/200
Proxime accessi[illegible]	164/200
Surgery.	
1st. Montefiore: Lieutenant A. Seddon, I.M.S.	80/100
2nd. Montefiore: Lieutenant H. C. D. Rankin, R.A.M.C.	75/100
Tropical Medicine.	
1st. Ranald Martin Gold Medal: Lieutenant A. K. Sinha, I.M.S.	86/100
Proxime accessit: Lieutenant R. B. Price, R.A.M.C.	84/100
Administration.	
1st. Marshall Webb Prize: Lieutenant H. C. D. Rankin, R.A.M.C.	97/100
Proxime accessit: Lieutenant R. B. Price, R.A.M.C.	88/100

Sir HAVELOCK CHARLES next distributed the prizes with a [illegible] recipient, and in his address [illegible] ouraged the young officers as [illegible] his remarks more particularly to those whose careers would lie in India. He said it was often asked why in life the race was not always to the swift nor the battle to the strong; the reason was that some men had not the tact and judgment to avail themselves of the chance when it offered. They failed through lack of character. The greatest of all assets was character. He was present at a similar meeting to this 31 years ago, and though he could not recall that any address was given on that occasion, [illegible] to town he travelled with [illegible] asked as to how to get o [illegible] a few seconds Sir Joseph Fayrer said: "Do what you are told; don't grumble; go where you are ordered." Of course, young men going to India would have troubles like everyone else, like the panel [illegible] Harley-street; but they [illegible] advice; and, further, th[illegible] thoroughly reliable—a most valuable characteristic for every officer. They were going to what he considered the most interesting country in the world. He wished them the best of good luck in the words of the Persian poet who said: "May the sweet waters of contentment spring up where'er you place your feet."

Surgeon-General BABTIE thanked the General Officer

He advised the greatest generosity to be extended to the injured worker, while at the same time the malingerer should be detected and exposed. His idea was that the injured man's doctor and the doctor of the insurance company (and this really represented the employer) should meet in consultation exactly as in any other occurrence of disease or accident, and decide on the case after discussion. Dr. Mitchell pointed out that in fractures two X ray photographs should be taken in different planes, and showed that unless this was done mistakes might arise, and he suggested that the insurance companies would be wise in their own interests to have an X ray installation fitted up and have radiographs taken. Finally, Dr. Mitchell exhibited a series of most interesting photographs which showed how much work could be done by people who had sustained great injuries to their hands. A hearty vote of thanks was passed to Dr. Mitchell for his address, which was rendered very much more interesting by an excellent series of lantern slides.

A resolution was subsequently carried to make Dr. J. Walton Browne, D.L., an honorary Fellow of the society.

A Correction.

In this correspondence last week there is an error on p. 1281, second column, four lines from bottom. The year 1900 should be *1909*. The year was given correctly in THE LANCET of Oct. 4th, 1913, p. 1025, in a note on the health of Belfast during 1912.

Nov. 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Hygiene of the Barber's Shop.

AT the last meeting of the Société de Prophylaxie Sanitaire et Morale, on the request of the Syndicat des Coiffeurs, Dr. Fonquet read a paper on the transmission of infection by hairdressers and their implements and the hygienic precautions to be recommended by the society in reference thereto. Dr. Fonquet recommended that cutting instruments should be washed in a 1 per cent. solution of carbonate of soda and wiped with a dry cloth. Brushes, combs, and shaving brushes should be freed from accumulated grease each evening by washing in ammoniated soap-water. Metallic instruments should be passed rapidly through a flame before being used again. Brushes and combs should be kept in a hermetically sealed retainer containing a saucer of 40 per cent. solution of formol. Rice powder should be applied only by means of a pad of sterilised cotton-wool, which should be destroyed at once. For the piece of alum commonly applied to cuts and abrasions in different persons powdered alum should be substituted, applied as above with cotton-wool, which should be destroyed after use. Barbers must be forbidden to sharpen their razors by stropping them on the palms of their hands. Regular customers should, if possible, have their own individual apparatus kept for their use alone. The society will be called on to consider these proposed measures and to submit them to the Conseil d'Hygiène with a view to their publication as a compulsory regulation for all barbers, to be posted in their shops. Of course, opposition to these measures is foreseen. Some time ago an attempt was made to impose the employment of a dry heat stove, heated by gas, in which scissors, razors, &c., were to be placed between their use on different persons. In practice for the most part the stove served only as a bid for confidence on the part of the customer, for the same razor and the same scissors always remained in it, while those used were spread out on a table, ostensibly having been sterilised and allowed to cool. Dr. Fouquet accompanied his report with microbiological evidence showing the need for the proposed measures. It had long been known, he pointed out, that syphilis, furunculosis, tinea, and perhaps alopecia, and other contagious diseases of the skin and scalp were transmitted at the barber's. M. Langlais had obtained from a shaving brush taken from a respectable barber's a culture containing 160,000 bacteria per c.c.; and the same observer showed that a razor before being rinsed furnished 7000 bacteria and 26,000 after having been stropped on the hand. As to the piece of alum Dr Remlinger had obtained 66,000 bacteria per c.c. from sterilised water in which it was dissolved.

The Use of Oxygen in the Insane.

Dr. Toulouse, of the lunatic asylum of Villejuif, has made, in conjunction with his assistant Dr. Puillet, some very interesting observations in reference to the use of subcutaneous injections of oxygen in persons suffering from nervous exhaustion, and even from mental diseases. In various cases of mental confusion with agitation, excitement, and insomnia, Dr. Toulouse has obtained remarkable results. The more acute the condition the more clearly marked are the effects. In simple cases of nervous exhaustion and in epileptics he had also had good results, though less marked and more transitory. The patients themselves, on regaining reason, described the sensation of well-being and immediate relief that followed the oxygen injections. The ultimate bearing of this method cannot yet be definitely settled, but it is worthy of study, at least in those cases in which an intoxication or an infection, which the organism cannot throw off, appears able to improve under very energetic oxidation. Dr. Toulouse does not despair of the successful use of this treatment even in cases of simple mental alienation.

Infant Mortality.

The report of Professor Achard to the Académie de Médecine on the working of the inspection of children of tender years has disclosed the fact that in 1911 the deaths of young children were 20,000 in excess of the usual average. This deplorable fact is attributed to the exceptional heat of the summer, and especially to an epizootic of aphthous fever which at that time attacked the cows in some parts of France, gravely altering the quality of their milk. The same causes have, moreover, led to similar results in neighbouring countries. These causes are temporary, and the later statistics already suggest a return towards the normal mortality. Professor Achard's report also confirms the statement of M. Pinard at the Académie de Médecine that in the provinces the use of the feeding-bottle was largely replacing breast nourishment. The *loi Roussel* forbids a wet nurse engaging herself out before her own child is 7 months old. This law, in force now for 15 years, is causing the almost total disappearance of hired wet nurses. The Academy, therefore, is considering at present a proposition to reduce to four months the time during which the nurse must reserve her milk for her own child.

Death of Professor Le Double.

Professor Le Double, of Tours, died recently from accidental asphyxia with carbon monoxide, the result of a defective heating apparatus. He was born in 1848 and studied medicine in Paris. He settled at Tours, where he became surgeon to the General Hospital in 1878 and professor of anatomy at the Medical School in 1888. In 1898 he was elected a corresponding member of the Académie de Médecine. He was one of the first anatomists of his time. His innumerable dissections revealed a large number and variety of anomalies in the disposition of the osseous and muscular systems and of the veins. He also published some notable volumes on morphological and historical questions relating to medicine. His work (in conjunction with Dr. F. Houssay) on the hairy type in the human race (*Les Vélus*) was very appreciatively reviewed in THE LANCET of August 10th, 1912. He also wrote on prehistoric medicine and surgery, on Rabelais as an anatomist and physiologist, and on Bossuet as an anatomist.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

A Magnificent Gift to the Johns Hopkins Medical School.

THE Johns Hopkins Medical School has received $1,500,000 from the General Education Board, which draws its supplies from Mr. John D Rockefeller. This is the biggest gift which the Board has made as yet to any one institution. The new foundation will be called the William H. Welch Endowment for Clinical Education and Research, in recognition of the great services rendered by Dr. Welch for medical education in America. The interest of the money is to be used for the salaries of the professors of medicine, surgery, and pædiatrics, their associates and assistants, and to provide the laboratories and clinical paraphernalia to enable them to carry on their work. The salaries paid will be fixed so as to give the holders an adequate sum for comfortable living, and they will be required to resign all private practice and to devote their lives to the work of research, investigation, and teaching. It is understood that the services of the three selected professors will be available for the public in certain circumstances, but gratuitously. Dr. W. S. Halsted, the present professor of surgery, has agreed to retain his chair under the new conditions.

A Urological Clinic for Johns Hopkins Hospital.

Mr. J. B. Brady recently offered to Johns Hopkins Hospital, Baltimore, the sum of £50,000 for the establishment of a special urological clinic. The first steps towards utilising this gift have now been taken, and contracts have been awarded for the erection of the building, which will occupy three storeys with a roof garden. Dr. Hugh H. Young is to have the direction of the clinic, which it is expected will be open to receive patients within a year.

The Study of Criminology.

Steps are being taken for the organisation of a National Society for the Study of Criminology, which is to be composed of psychologists, sociologists, and medical experts. The study of criminology is becoming more widely extended, and evidences of an awakening in regard to it are forthcoming from many quarters. Among others mention may be made of the recommendations of the Committee on Criminal Punishment of the Chicago Medical Society, suggesting the separation at all times of misdemeanants from felons; the hastening of grand jury and final trials; the extension of the reformatory idea to all criminals except incorrigibles and those charged with capital offences; the appointment of an Illinois State Sentencing Committee to classify all criminals; and the arousing of the interest of the women of the State in their sisters who have undergone penal sentence, with a view to preventing their drifting in crime or vice.

A Woman Research Fellow at Yale University.

Th[illegible] lish [illegible] Pou[illegible] the Scandinavian countries and the United States, has established six Fellowships, to which nominations are made by th[illegible]nts, to enable Scandi[illegible] work in the American [illegible]nent has recently appointed the first woman Fellow, in the person of Miss Ellen Gleditsch, a pupil and associate of Madame Curie in Paris, to study radio-activity in the laboratories of Yale University.

Colonel Gorgas goes to South Africa.

Colonel Gorgas, of the United States Army, whose work as a sanitarian in subduing yellow fever in Cuba and later in rendering possible by sanitary measures the completion of the Panama Canal, where he is chief sanitary officer of the Canal Zone, has received leave of absence to proceed to South Africa to investigate the conditions obtaining in the mines there, where the mortality is notoriously heavy. Colonel Gorgas is a charming colleague, and will doubtless be heartily welcomed by the medical authorities in charge.

The late Dr. James Egan, of Springfield, Ill.

Dr. James Egan, who died from nephritis a little while ago in Springfield, Ill., aged 53, had served as secretary of the Illinois State Board of Health since 1897. Since 1901 he had also been a member of the Board and since 1909 its treasurer. He was an aggressive opponent of illegal practitioners of medicine, incompetent midwives, and "diploma mills." He was a native of Massachusetts but came to Illinois in 1887, and graduated in medicine at the Northwestern University Medical School (then the Chicago Medical College) in 1893. For four years he held appointments under the Chicago Health Department, becoming later secretary of the State Board of Health of Illinois. He was a first lieutenant of the U.S. Army Medical Reserve Corps. Notwithstanding a certain aggressive combativeness of disposition he made many firm and devoted friends to whom his loyal nature endeared him. THE LANCET has on more than one occasion commented editorially on the sensible and practical *Bulletins* which he issued from the Illinois State Board of Health.

Death of Professor Reginald Heber Fitz.

In the death of Dr. Reginald Heber Fitz, which took place recently from gastric ulcer, the medical profession in America loses one of its distinguished pathologists. Dr. Fitz, who was born in Massachusetts in 1842, graduated at Harvard University, and studied subsequently in Vienna, Berlin, Paris, and London. On his return to America he was appointed to the staff of the Massachusetts General Hospital in Boston and became instructor, and subsequently professor, of pathological anatomy in the Medical School of Harvard. In 1877 he became physician to the hospital, and in 1892 professor of medicine at Harvard. He did pioneer work on appendicitis and on pancreatic diseases.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

First Dominion Medical Council Examinations.

Dr. R. W. Powell, registrar, Dominion Medical Council, Ottawa, announces the results of the examinations held in Montreal on Oct. 7th. Seventy-one candidates presented themselves and 44 were successful. Eight were referred to the Council, having failed to qualify in not more than two subjects, and 19 were rejected. Most of the successful candidates were from the provinces of Ontario and Quebec. New Brunswick furnished 1, Alberta 1, British Columbia 1, and 2 were from the United States.

Winnipeg General Hospital.

A by-law will be submitted to the ratepayers of Winnipeg, Manitoba, in December for $275,000 for the purposes of the General Hospital. Recently a new wing was opened and other extensive additions made which bring the capacity of the hospital up to 478 beds. The cost of these additions approximated $605,000 on the main building, $54,000 on a nurses' home, and $14,000 on a new residence for the superintendent. Of the total amount only $460,000 have been received by the board of trustees, and as there is a mortgage of $60,000 not less than $275,000 will meet the present requirements. The provincial government will also likely be approached for a grant, as a good many patients come from different points throughout the province.

An Epidemic of Jaundice.

During the months of March and April, 1911, Dr. Malcolm Mackay, of Sherbrooke, Quebec, had 17 cases of acute jaundice under his care. Five were males and 12 females, and 13 of the total number were between the ages of 15 and 25 years. No two cases occurred in the same house. Hearing of other cases at the same time, Dr. Mackay sent a [illegible] ing 5 cases of every sort per annum to every 2000 according to *Leslie's statistics*, Sherbrooke should have had about 43 cases in the course of the year. But there were 99 cases reported in two months. In all the cases there were 34 males and 65 females. Of children under 15 years of age, there were 45 cases; 13 cases in adults over 25 years; the remaining 41 being between 15 and 25 years. More than one case in a house was reported six times by one physician, three times by another, and once by another, while a fourth had five cases in a small orphanage. The greater majority of the cases were found in one ward of the city. Dr. Mackay draws the following conclusions: The disease is infectious; gastro-enteritis is present; the jaundice is of the *obstructive type* characteristic of catarrhal jaundice; the disease is possibly contagious.

The Canadian Hospital Association.

The a[illegible] was held [illegible] to 22nd [illegible] superint[illegible] opening [illegible] discussi[illegible] coroner averred that the sale of these drugs had increased rapidly in the city during the past few years, and called for an amendment of the *Canadian criminal code* to deal with this question. The President regretted in his address that hospitals were so parsimonious that they would not send their superintendents to these annual meetings. He also

An Address

ON

THE DEGENERATION OF THE NEURONE IN THE LIGHT OF RECENT RESEARCH,

ESPECIALLY IN RELATION TO SYPHILIS AND GENERAL PARALYSIS.

Delivered at Birmingham at the Inaugural Meeting of the Midland Medical Society, Session 1913-1914.

BY F. W. MOTT, M.D. LOND., F.R.C.P. LOND., F.R.S.,

PATHOLOGIST TO THE LONDON COUNTY ASYLUMS.

MR. PRESIDENT AND GENTLEMEN,—Allow me to thank you for inviting me to follow the long list of distinguished members of our profession who have had the honour of giving an address at the annual inaugural meeting of the Midland Medical Society. I must first ask your permission to extend the title of my address in order to limit the scope to a subject in which I have long been interested—viz., the relation of syphilis to the degeneration of the neurone, especially in general paralysis, which owing to recent discoveries and the importance of the subject, particularly at the present time, necessitates a fuller discussion than other causes of degeneration of the neurone.

DEGENERATIONS OF THE NEURONE.

The term "neurone" implies a nervous unit—that is, a nerve cell and all its branches. The nervous system is made up of countless millions of nervous units, each one existing as an independent organism in contiguity but not in continuity. The neurones are genetically and trophically independent cellular organisms arranged in functionally correlated systems, communities, and constellations. There are two types of neurones, one in which the axis-cylinder process leaves the grey matter and acquires a medullated sheath—this is the first type of Golgi; the other, the second type of Golgi, in which the axis-cylinder process does not leave the grey matter. The nutrient and supporting tissues—viz., the blood-vessels, lymphatics, and neuroglia tissue—make up the histological elements.

Degeneration of the neurone may occur from an inherent lack of durability of certain correlated functional systems, as occurs in certain diseases which affect members of families at the same age in life and often in generation after generation—e.g., Huntington's chorea, hereditary ataxy. Degeneration of the neurone may result from direct injury or local extension of inflammation or by ischæmic softening due to obstruction of the blood supply by vascular occlusion; the degeneration that results therefrom is secondary. But when for whatever cause nervous tissue disappears the neuroglia always reacts by a nuclear and fibrillar proliferation—a law formulated by Weigert in 1890. The replacement of the nervous tissue by the neuroglia tissue causes a "sclerosis." But it is hardly necessary to remind you that the term "sclerosis" in the sense of a neuroglia proliferation being the primary cause is incorrect; the sclerosis is the effect, not the cause. Certainly there is a primary gliosis due to embryonic tissue taking on active growth, but the destruction of the neurones in syringomyelia is not caused so much by the gliosis as by hæmorrhages occurring in the glial tissue.

Now we recognise a certain number of primary degenerations of the nervous system characterised by insidious onset, progressive character, and a tendency sooner or later to a fatal termination, generally hastened by intercurrent disease or secondary microbial infections due to complications. I will put on the screen a slide to illustrate some of these primary degenerations. A pure primary decay of the neurone has been termed by Sir William Gowers "abiotrophy." Many of these [illegible] are associated with chronic [illegible] ad it is very difficult to say [illegible] decay of the neurone or are the result of it; certainly a proliferation of neuroglia tissue may result from simple atrophy and decay of the neurones, but a perivascular lymphatic infiltration with lymphocytes and plasma cells are evidence of a reaction to the poison.

Now there are two diseases which I have studied for many years in which this perivascular cell infiltration, together with neurolgia proliferation, is particularly marked and more or less universal in the central nervous system. They are the diseases caused by two specific protozoal organisms—the trypanosoma gambiense, the organism which causes sleeping sickness, and the spirochæte pallidum, the organism of syphilis.

Sleeping Sickness.

When I first published an account of the histology of sleeping sickness 14 years ago I pointed out the close similarity in the histological changes of the central nervous system to syphilitic meningo-encephalitis. I will show you now on the screen slides illustrating this, also one of experimental sleeping sickness. You will observe that the same perivascular infiltration with lymphocytes and plasma cells occurs in sleeping sickness, in syphilitic meningo-encephalitis, and in general paralysis of the insane (Figs. 5 to 9). In the last-named disease we have, as Noguchi says, a parenchymatous meningo-encephalitis.

The knowledge of the cause of sleeping sickness began with the discovery by Castellani of the trypanosoma gambiense in the cerebro-spinal fluid of five cases of sleeping sickness in Uganda, and the importance of this discovery is best shown by Sir David Bruce's acknowledgment in the fourth volume of the Sleeping Sickness Commission.

> This *most interesting discovery* of Dr. Castellani's, which was due to his introduction of the method of centrifuging the cerebro-spinal fluid in his search for streptococci, has been of the utmost value to the present Commission. It put them at once on the right track, and led to the easy and rapid elucidation of the hitherto mysterious disease. Without knowledge of his observation they might have worked for months in the dark, and, *in truth, they might even have* returned to England still ignorant as to the true cause of the disease.

Castellani had already given it as his opinion that a streptococcus was the cause of the disease, he believing that the trypanosome, *like the filaria* perstans, was an accidental concomitant. If he had been able to extend his observations he might have changed his opinions. I mention this because a letter appeared in the *Times* disputing Professor Ehrlich's right to give *any credit to Castellani* for the discovery of the cause of the disease.

A large number of specimens of brains of cases of sleeping sickness were sent to me to examine by the Commission, and I could add little or nothing to my original description of the histological changes found in two cases of Manson which were in Charing Cross Hospital. I never succeeded in finding the trypanosomes in sections, but I have seen them in brain smears; the trypanosomes were always found in the cerebro-spinal fluid by Sir David Bruce.

Now the trypanosome of sleeping sickness is, comparatively to the spirochæte pallidum, a large organism, and therefore it is not surprising that no one before Noguchi was able to find the specific organism of syphilis in the brains of general paralytics; although to my mind the facts which had already accumulated since Fournier pronounced this disease to be parasyphilitic seemed to be overwhelming proof that if there were no syphilis there would be no general paralysis.

CLINICAL AND ETIOLOGICAL FACTS SUPPORTING THE SYPHILITIC ORIGIN OF GENERAL PARALYSIS AND TABES DORSALIS.

1. A history of syphilitic affection, usually of a mild form as regards secondary and tertiary symptoms, can be obtained in as lar[illegible] cases of general paralysis as in [illegible] skin lesions. 2. A correlation of the incidence of syphilis and the incidence of general paralysis in the two sexes according to the social grade. 3. In 60 cases of the juvenile form of general paralysis I found evidence of congenital syphilis either in the family history or signs on the body of the patient in nearly every instance, and in not one could it be excluded. In the juvenile form the sexes are equally affected. Mental stress, alcoholism, and sexual excesses, the previously attributed causes, can be excluded. 4. I showed that Fournier was right in asserting that tabes and general paralysis pathogenetically were one and the same disease, affecting different parts of the nervous system, for I collected 70 cases of tabo-paralysis, and I found that some began as tabes and ended in general paralysis; in others the spinal and cerebral symptoms started simultaneously; while again in others it began with optic tabes and ended in spinal tabes or tabo-paralysis. About 10 per cent. of cases of tabes end in tabo-paralysis. 5. The most convincing proof of the syphilitic nature of general paralysis was Krafft-Ebing's inoculation of nine paralytics with no history and no signs on the body, none of whom were capable of re-infection. In all my very large experience I have never seen a primary sore or secondary eruption on a paralytic.

This chain of circumstantial evidence was strong enough for most [illegible] eminent authorities such as Si[illegible]. Dr. Drummond, and many others were convinced, as I was, that if there were no syphilis there would be no tabes or general paralysis.

THE SEARCH FOR THE SPECIFIC ORGANISM IN THE BRAIN.

Then came the discovery of the spirochæta pallida of syphilis by Schaudinn, and the successful inoculation of anthropoid apes by Metchnikoff, Hoffmann, Neisser, and others, which was extended to other animals such as apes and rabbits. This was followed by the introduction of the Wassermann reaction, and the blood of persons who were reacting to the syphilitic organism was shown to have complement fixation. It was soon found that general paralytics invariably gave the reaction in the most marked manner, and later Plaut showed that [illegible] gave a positive reaction in 96 [illegible] um giving it in every case. Indeed, the cerebro-spinal fluid was much more certain to give a positive reaction than syphilis of the nervous system. My assistant, Dr. J. P. Candler, has found 98 per cent. of paralytics give a certain positive reaction of the fluid, and the results have been already confirmed in over 200 cases by post-mortem examinations.

The introduction of the ultramicroscope led us to look for the spirochæte in the cerebro-spinal fluid in a number of cases, but we did not meet with success. I also made a great number of preparations of sections of the brain by the Levaditi method, but, like Minea and Marinesco, who examined 30 cases of general paralysis, I was unsuccessful in finding the spirochæte. I therefore concluded that in all probability there was a latent granular form, and in the fourth volume of the System of Syphilis—"Syphilis of the Nervous System"—I put forward this view, supporting it by the fact that I had seen in smear preparations enormous numbers of chromidian granules; likewise in sections of syphilitic papules, where only a few spirochætes were seen, I have observed these granules. But my main argument was based upon the important observation by Leishman that the spirillum of tick fever exists in a granule form in the cells of the body of the tick, and he could cause these granules to develop into spirillary forms. Again, Neisser was able to infect monkeys with the marrow of bone of infected animals, although the most diligent search showed no spirochætes. Noguchi himself thinks there may be a granule form; in fact, his culture experiments seem to indicate such. Moreover, Balfour and O'Farrell have stated that they have observed a shedding of granules after acting upon spirochætes with salvarsan. The paper published in February by Noguchi and Moore, in which it was shown that Levaditi-silver-stained-preparations of 70 cases of general paralysis showed spirochætes in 12 of them, was an epoch-making discovery.

When I was at the Rockefeller Institute in April, Noguchi was good enough to give me one of these preparations, which left no doubt in my mind of their existence. Since this discovery by Noguchi we have a new conception of the disease on the sure ground of direct observation, yet there are still many facts unexplained; nevertheless, all the evidence points to the fact that the term "parasy[illegible] a post-syphilitic affection, must be [illegible] term *parenchymatous syphilis*. Noguchi has examined another 130 cases of general paralysis, and in this second series he found the spirochætes in 36, making in all 48 out of 200. In 6 cases he examined fresh brains by means of the ultramicroscope, and in one of these he found spirochætes. In 12 cases of tabes he found the organism in one only. Marinesco and Minea have reported that 1 case out of 26 yielded a positive result by the silver *method*. This case showed nests of spirochætes, as many as 60 in one field of the oil immersion being counted. I throw on the screen a photomicrograph of a specimen sent me by Professor Marinesco. (Fig. 5.)

Marie, Levaditi, and Bauchowski have reported 3 positive results out of 30 cases of general paralysis by the silver method. In a more recent publication they claim to have shown that spirochætes are constantly present in the brains of general paralytics dying in seizures. They emphasise the importance of a systematic examination of all the convolutions of the cortex until a positive result is obtained. They do this by sections, by films prepared from an emulsion of the cortex and subsequent examination by the Indian ink method or the silver method of Fontana. They found spirochætes in all the 7 cases examined. They observe that if one can localise the muscular epileptiform seizures a guide will be obtained of a focus of spirochætes in the neighbourhood of the portion of motor area affected. I show a preparation kindly sent me by M. Marie. (Fig. 4.) Forster and Tomasczewski obtained 2 positive results out of 4 cases in which the material was taken from the patient by the Neisser-Pollak puncture method and examined by the ultramicroscope.

NOGUCHI'S EXPERIMENTAL OBSERVATIONS.

Before referring to my own observations I will give a *résumé* of Noguchi's experiments relating to the transmission of the spirochæte pallidum obtained from the brains of general paralytics to the rabbit, and the experimental production of syphilitic encephalitis in this animal.

Noguchi inoculated into the testicles 36 rabbits with the emulsion of six different specimens of brains of general paralytics in the fresh state. At the end of 97 days in one case and 102 days in the other a small but typical induration of the testicle and scrotal skin occurred. In the first case the spirochætes were few, in the second they were abundant. It is interesting to note how slow was the development as compared with the transmission by infection made with material obtained from a chancre or secondary lesion; in the latter case the lesions generally appear after an interval of four to six weeks, rarely two months elapse.

THE EXISTENCE OF THE PARASITES IN THE PARENCHYMA OF THE NERVOUS SYSTEM IN RELATION TO THEIR RESISTANCE TO THE ACTION OF DRUGS.

This interesting observation of Noguchi may be correlated with the many facts which seem to point to the specific organism that produces general paralysis being either a form which has been modified by the widespread use of mercury or modified by passing through the bodies of individuals who have acquired resistance. A number of instances of infection have been reported which seem to point to the possibility of a specific organism; the most convincing being that of Brosius in which seven glass-blowers were infected, four of whom ten years later suffered with tabes or general paralysis. Certain it is that the average time after infection in general paralysis and tabes is 10 years, and the signs and symptoms of the disease externally manifest in the form of skin and bone lesions are as a rule either absent, mild, or obscure; whereas in syphilitic brain and cord disease the great majority of the cases occur within the first four years after infection, the greatest percentage occurring in the first and second years. Whereas the signs and symptoms of the latter are coarse and obvious and with generally well-marked skin eruptions amenable to treatment, the former—the so-called parasyphilitic, or, as I shall prefer to call them, parenchymatous syphilitic disease—are late (quaternary) and comparatively unamenable to treatment. Is this because they are mercury-fast organisms, or is it because they exist in a latent granular or intracellular form in the parenchyma of the nervous system, where they cannot be attacked by the drugs such as arsenic, mercury, and antimony? By analogy this does not seem improbable, seeing that in sleeping sickness when once the trypanosome has invaded the nervous system, atoxyl and other arsenical and antimonial preparations which were intravenously injected fail to kill the parasite and arrest the progress of the disease. Moreover, there is other evidence in favour of this conclusion. Arsenic is not found in the brain when large quantities of arsenic have been taken in cases of poisoning; it has not been found in the fluid after injection of salvarsan intravenously. The late Professor Goldmann has shown that the choroid plexus intercepts dyes which have been injected intravenously in large quantities, 100 c.c. of a 1 per cent. solution of trypan blue, whereas 1–2 c.c. of 0·5 per cent. solution injected by lumbar puncture stains the whole cerebro-spinal axis except the cortex, penetrating and staining all the neurones. This, as I shall tell you later, has led to the idea of a new method of treatment, not by injecting weak doses of salvarsan or neosalvarsan intrathecally, for this would be a most dangerous proceeding; to kill the parasites you might kill the neurones and the patient.

The only case of trypanosomiasis ugandensis that I have heard of as having recovered was a Sikh whose brain was sent to me for examination. He lived five years after infection and was treated for a long time—18 months—with atoxyl, then with mercury, for he became intolerant of arsenic and had contracted syphilis. Three years after infection his fluid was examined by Sir David Bruce and found free of trypanosomes and he showed no signs or symptoms of sleeping sickness; he died two years later. I examined his brain and found no signs of perivascularitis or neuroglia proliferation —histological changes which were present in every case, 30 in all, that I had previously examined and which during life had exhibited the characteristic lethargy.

These facts show that the presence of the trypanosome in the central nervous system is necessary to produce the meningo-encephalitis characteristic of the disease, although to my mind it is possible that toxins may pass into the central nervous system along perivascular and perineural lymphatics, as Orr and Rows have shown experimentally.

FURTHER EXPERIMENTS OF NOGUCHI.

Noguchi has shown that the central nervous system of monkeys and rabbits is very resistant to syphilitic infection, even when the virus is introduced directly into the cerebral substance. Most animals remain in perfect health during an indefinite period after the intracerebral inoculation of spirochæte pallidum. Noguchi conceived the idea that it was necessary to sensitise these animals by repeated intravenous injections with dead and living spirochætes; this he did for five months. At the end of this time he made an intracerebral inoculation or subdural insertion of an emulsion of minute particles of testicular syphiloma of the rabbit, rich in spirochætes. Twelve sensitised and 4 normal rabbits were employed, all of which remained healthy for two months; then some of the sensitised rabbits showed symptoms. The animals were killed and 3 of those which had been sensitised showed cerebral changes not unlike those of a syphilitic meningo-encephalitis. For my own part, I am doubtful whether these experiments prove very much one way or the other as regards the production of general paralysis in animals.

PERSONAL OBSERVATIONS.

I will now refer to the recent work concerning the existence of the spirochæte in the brains of cases of general paralysis which has been done under my direction at Claybury; also I will endeavour to demonstrate the difference in the pathogenesis and histology of syphilitic meningo-encephalitis and general paralysis and syphilitic meningo-myelitis and tabes dorsalis. I will also compare the histology of sleeping sickness, a trypanosome infection, with the syphilitic spirochæte infections, and the deductions which can be made therefrom. Lastly, I will call your attention to an inquiry into the incidence of general paralysis in the different parishes and districts of the county of London.

SPIROCHÆTES IN THE BRAINS OF GENERAL PARALYTICS.

Having failed to find the specific organism in sections stained by the Levaditi method after a diligent search of numbers of sections from numbers of cases—in this search I was aided by my assistant Mr. Charles Geary, Dr. Fisher, and Major Fink—I resolved to adopt the Indian-ink method (Burri); and by this method I soon obtained apparently positive results. I say [illegible] must be admitted that delicate [illegible] may be mistaken for spirochætes, and unless these spiral forms have been observed in the living state moving on the dark-ground microscope convincing proof of the presence of spirochætes would be wanting. Yet I feel convinced they were in the light of further researches by the Fontana method and the ultra microscope.

I have thought that active pullulation of the specific organisms might be associated with epileptiform seizures, and in support of this I may observe that I have found that unilateral convulsions of a severe nature were at the necropsy associated with a great wasting of the corresponding hemisphere. For example, I have found after prolonged right-sided seizures a marked speech affection and a hemiparesis; at the post-mortem examination the left hemisphere has in some instances of this kind weighed as much as 100 grm. less than the right. In the light of recent researches of Noguchi it is probable that the active development of the spirochætes leads to the production of toxins which cause a rapid destruction of the neurones in two ways—firstly, by the direct destructive effects of the toxins on the neurones; and secondly, by irritation and proliferation of the cell elements of the perivascular lymphatic sheaths, the capillary endothelium, and the neuroglia cells, the perivascularitis and capillary changes causing blood stasis and destructive effects on the neurones secondary to these inflammatory changes

But to return to the demonstration of spirochætal foci in the brains of paralytics. Having this hypothesis of association of active proliferation of the specific organism and the onset of seizures I wrote an encyclical letter to the superintendents of all the ten asylums asking them to forward me the brains of patients who just prior to death had had seizures, and from these brains, which numbered in all 11, I obtained by the Indian-ink method spiral forms in 8 cases. Of 7 cases dying at Claybury in the ordinary routine and not selected, in 3 spiral forms were found (*vide* illustration). Portions of all these 18 brains were fixed and stained by Noguchi's modified silver method and sections made; so far specimens from eight brains have been examined but without results; indeed, the fibrils in many of the specimens are stained as well as in Levaditi preparations.

My assistant, Mr. Geary, has now succeeded in staining films with the Fontana Tribondeau silver method, and we have obtained excellent results in 3 cases; in one of these—a brain sent from Horton, which was comparatively an early case—numbers of spirochætes were found in film preparations (*vide* illustration) of the second frontal convolution, but from no other of many regions examined. This shows the truth of Marie, Levaditi, and Bauchowski's observation that all the convolutions of the cortex require to be examined systematically. The spirochætes of this case four days after death were also observed moving, it is true only sluggishly, by means of the ultra-microscope. Spirochætes were not found in films from the second frontal when the brain was received; but 24 hours later, when the substance was soft and a certain amount of decomposition had occurred owing to invasion of other organisms, they were found in abundance in this one region.

Seeing that fœtal tissues containing a great abundance of spirochætes are generally decomposed and contain numbers of other organisms, as also chancres and the enlarged lymphatic glands, it is possible that the secondary microbial invasion by aerobic organisms may possibly favour in some way the development of the non-aerobic specific organisms, as we know is the case in tetanus. Certainly my experience teaches that pneumonia, dysentery, septicæmia, and other intercurrent secondary microbial infections are especially liable to be associated with seizures, not necessarily generalised, but often unilateral in character.

Further experiments and observations which I am now making will, I hope, help to decide whether the hypothesis of a latent granule form, which under favouring circumstances develops into a spirochætal form with production of toxins, is true or not. The great difficulty is that the search for spirochætes in the brain is like looking for the proverbial needle in a haystack; not finding does not mean non-existence. The investigation is attended with great technical difficulties, and there is still much to be done before we can fully understand the pathogenesis and pathology of these late syphilitic diseases of the nervous system.

INTRATHECAL INJECTION OF PATIENTS' SERUM AFTER SALVARSAN TREATMENT.

In respect to the early acute infection of the central nervous system, I may mention that I recently had under my care a case of gummatous meningo-encephalitis. Infection occurred in February last, and in spite of intramuscular injections of salvarsan and mercury severe cerebro-spinal symptoms set in in September. The cerebro-spinal fluid showed a great abundance of lymphocytes, and a spiral form which resembled a short spirochæte was found in one of the Indian-ink preparations of the centrifuged deposit. As I could not find spirochætes moving with the dark-ground illumination this is not claimed as convincing proof. The cerebro-spinal fluid, like the blood, in this case yielded a very marked complement fixation. He subsequently received an intravenous injection of 0·4 grm. neosalvarsan with great improvement, but the greatest improvement resulted from an intrathecal injection of serum taken one hour after another dose of neosalvarsan had been administered; subsequent to this the fluid became less positive and the lymphocytosis disappeared.

The serum was tested for arsenic and yielded no result; the [illegible] conclusion being that the action of the seru[illegible] antibodies in

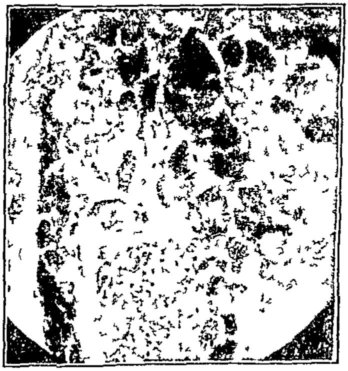
FIG 9



Section of brain in general paralysis showing longitudinal section of vessel with active proliferation of plasma cells (× 750)

the blood and not to the arsenic. But seeing that I have found that intravenous injections and even intramuscular injections of salvarsan may convert a positive Wassermann reaction of the fluid in general paralysis into a negative reaction, and thus account for the improvement, it is necessary that the serum of another individual who had received an intravenous injection of salvarsan should be injected into the lumbar subarachnoid sac before it could be claimed that the antibodies in the serum were the cause of the improvement. Dr. Swift, of the Rockefeller Institute, who claims to have obtained very hopeful results by this method of treatment in tabes dorsalis, said at the International Medical Congress that he had done this with equally satisfactory results. If this be true it would appear that mercury and arsenic are spirillocidal either by causing the development of antibodies or by furthering their spirillocidal action. Dr. George Robertson, of Morningside Asylum, from his experience, does not claim to have attained a cure, and is quite judicial in his statement regarding the effect of this treatment in general paralysis, for he says:—

> Although success has not been obtained there are hopeful indications, for it appears that the disease process, if not suppressed, is at least touched in half the cases. The decrease in the lymphocytosis, the diminution in the intensity of the Wassermann reaction, and its disappearance for over a year in some cases are hopeful signs of the most convincing character.

Dr. Fisher, of the Rockwood Hospital, Kingston, Canada, who for some months past has been working under my direction at the Pathological Laboratory, Claybury, had the idea of treating general paralysis by this method, and in the spring of 1912, by the kindness of the superintendent, Dr. Ryan, Dr. Fisher took 7 cases of advanced general paralysis and rendered the blood negative to the Wassermann reaction by repeated intravenous injections of salvarsan. Then under rigid antiseptic precautions he withdrew 15 to 20 c.c. of blood from the median basilic vein of the patient's arm, placed this in a cool chamber for one hour, separated the clot, and centrifuged the serum for half an hour in sterile tubes. Next he performed lumbar puncture and withdrew cerebro-spinal fluid of an amount equal to that of the serum to be injected, which is slowly introduced, being kept at the body temperature. The patient is allowed for one hour to lie flat on his back without a pillow and with the foot of the bed raised. This treatment was repeated every week for the first three months, then every two weeks for the next four months. No untoward symptoms occurred in any of the cases under treatment, and he has learned that the cases have greatly improved, and apparently there has been an arrest of the symptoms so far.

In the Oliver-Sharpey lectures which I delivered at the Royal College of Physicians of London in April, 1910, I gave many reasons from experiment and observation why it seemed probable that the cerebro-spinal fluid functions as the lymph of the brain. I also pointed out that, inasmuch as normally it contains no proteids or cell elements, if microbial invasion occurred it tended to spread rapidly because the fluid normally contained no bactericidal action nor leucocytes capable of combating microbes. These experiments of introducing serum of patients, which presumably contains antibodies, rest therefore upon a scientific basis if my conclusions are correct. At the same time it is difficult for the serum to arrive at the crannies in the cortex by injecting it by lumbar puncture into the subarachnoid space, for Goldmann's researches with trypan blue show that the cortex is unstained when the dye is introduced by lumbar puncture. He found, however, that the cortex is well stained when the dye is introduced by trephining the calvaria. It is possible that by repeated injections, as in Dr. Fisher's experiments, the antibodies may reach the cortex by lumbar puncture. Goldmann's work, however, shows the desirability of trying the method of introducing the serum directly into the subdural or subarachnoid space of the cortex. Unfortunately, I have not the authority to try this in my capacity of pathologist to the London County Asylums.

THE WASSERMANN REACTION.

I have already mentioned that in practically every case of general paralysis a positive Wassermann reaction is obtainable in the cerebro-spinal fluid, whereas not more than 50 per cent. of the cases of tabes yield a positive reaction. Why is this? In my opinion the reaction in the cerebro-spinal fluid is evidence of the existence of the parasites or their toxins in the central nervous system. I consider that it is the toxins produced by the active generation of the parasites which cause the reaction, the degeneration of the neurones, and the active proliferation of the lymphocytes, plasma cells, and neuroglia cells. For several reasons I consider it is a reaction of the neurones which gives rise to the euglobulin in the fluid that serves as a complement fixative. Firstly, because the toxins of other specific organisms, for example, tubercle, give rise to lymphocyte, plasma cell, and neuroglia proliferation without producing complement fixative in the fluid. Secondly, because some cases—in fact, the majority of cases of cerebro-spinal syphilis, even cases with active meningitis and enormous numbers of lymphocytes in the fluid—nevertheless give a negative Wassermann reaction, and there is no complete parallelism between lymphocytosis and degree of complement fixation. The experiments of Levaditi and Yamanouchi, however, show that it is the toxin of the spirochætes, and not the parasites themselves, which induces the typical lymphocyte and plasma cell reaction. Thus they introduced a small portion of infected cornea of a rabbit containing abundant spirochætes into the anterior chamber of the eye of a healthy rabbit, and they observed a characteristic cell reaction in the cornea of the normal rabbit before there was an invasion by spirochætes. This experiment shows that a localised nest of spirochætes in the cerebro-spinal axis or even outside the central nervous system, provided the toxins can be conveyed by lymphatics, can set up the characteristic cell reaction in the perivascular spaces of the nervous system, each fresh dose of toxin leading to a remission of symptoms and decay of nervous structures.

We know that normally the choroid plexus does not let this toxin pass into the cerebro-spinal fluid any more than it does the antibodies, for the blood may give a very strong reaction in cases of syphilis, and yet the cerebro-spinal fluid not show the slightest trace of reaction. Now the cerebro-spinal fluid in great part is secreted by the choroid plexus into the lateral ventricles; consequently fluid withdrawn from the lateral ventricles should give a less marked reaction than that withdrawn by lumbar puncture, for the latter would have been in contact longer with the nervous tissue. Acting upon this hypothesis I asked my assistants, Dr. Candler and Mr. Mann, to examine a number of cases to test its validity. In 38 cases the fluid was withdrawn as soon after death as possible from the lateral ventricles and by lumbar puncture: the result obtained in all the instances was to show that the fluid obtained by lumbar puncture was from two to ten times as strong in linking up complement as that from the ventricles. Doubtless, if the fluid could be obtained as it was secreted during life into the lateral ventricles no specific globulin would exist in it.

Tabes being a much slower decay of the neurones, and limited to the posterior spinal afferent neurones in the great majority of cases, presumably is occasioned by small doses of toxin finding entrance to the posterior columns by limited and defined channels; indeed, it is conceivable that the syphilitic toxin may arise in lesions of the thoracic or abdominal aorta which, passing along the lymphatics of vessels, gains access to the lymphatics of the spinal cord, the circulation of the lymph being along the course of the afferent roots. This seems probable from the experiments of Orr and Rows, who have, by tying celloidin capsules containing microbial toxins on the sciatic nerve, produced a perivascularitis in the posterior columns with degeneration of exogenous afferent systems like those of tabes. Possibly the perivascular lymphatics of the carotids may convey toxins or even the specific organisms to the fronto-central region of the brain in cases of general paralysis. This is a not improbable source of infection, for if skin lesions of syphilis are rare in this disease, syphilitic nodular fibrosis of the aorta is extremely common.

LESIONS IN EARLY AND LATE STAGES.

A comparison of the lesions of syphilitic disease of the brain and cord in early stages after infection with those occurring late, on an average 10 years after infection, shows that in both there is the same perivascular infiltration with lymphocytes and plasma cells; this is the reaction to the toxin produced by the parasite. In syphilitic brain disease there is also an endarteritis, sometimes localised, sometimes universal, and it is the blocking of the vessels by this inflammatory condition, especially when associated with thrombotic occlusion, which occasions the symptoms of so varied and obtrusive a character and sudden in onset. So also in focal meningomyelitis the localised decay of neuronic structure giving rise to paraplegia is due to obliterative endarteritis more than to the meningeal and peri-vascular inflammatory changes. If the vessels are not damaged extensively remarkable curative results by specific treatment are obtainable. The Argyll-Robertson pupil so characteristic of tabes and general paralysis is not seen.

In general paralysis examination of the vessels of the brain seldom shows any evidence of endarteritis; if there is any extensive vascular inflammation it is in the capillaries, where undoubtedly the endothelium undergoes active proliferation and budding; the reason for this cannot be the toxin circulating in the blood, otherwise the endothelium of the arteries and veins would show it. Probably the specific toxin is in all the interstices of the nervous tissue wherever the cerebrospinal fluid irrigates; thus it comes in contact with the capillary endothelium and excites its active proliferation, with capillary blood stasis, a histological condition that is especially characteristic of general paralysis.

I have met with a few cases of syphilitic brai disease, which have terminated in typical gener paralysis, and St[illegible] has recorded several [illegible] general paralysis [illegible] the mos consistent naked-eye phenomenon, which is not see to anything like the same degree in syphili brain disease nor in sleeping sickness, is th granular condition of the ventricles, especiall the fourth ventricle. This indicates the prolonge existence of an irritant toxin in the cerebr spinal fluid. The greater the wasting of th brain the more pronounced is this chang The wasting of the fronto-central convolution and of the whole cerebral cortex, but to less degree, is a characteristic feature of thi disease (general paralysis) as compared wit syphilitic brain disease. Doubtless this is in pa due to the vascular changes, but inasmuch as i sleeping sickness the perivascularitis and meningiti may be as extensive as, and even more univers and extensive than in general paralysis, it must b concluded that there is also in this disease primary and progressive decay of the neurone owing to the continuous action of the toxin sensitising the nerve cells and causing them to react such a degree that the normal metabolic equilibriu is destroyed and degeneration ensues, so tha we have, as Noguchi asserts, a parenchymatou encephalitis.

THE INCIDENCE OF GENERAL PARALYSIS IN THE POPULATION OF LONDON.

If it could be assumed that 2–3 per cent. o persons who acquired syphilis developed genera paralysis it might help us to estimate approximately the extent of syphilis in a population; fo inasmuch as general paralysis is a disease fata within a few years of admission to the asylum accumulation of cases suffering from this diseas does not occur, consequently the death-rate pe annum is about equal to the admission rate. I wi throw on the screen a lantern slide showing th incidence of general paralysis in the genera admissions to the London County Asylums durin the years 1911–1912 from the parishes north an south of the Thames, east and west; I will poin out the main results which these tabulated statistic show.

North of the Thames—West-end parishes. Total population equals 1,376,083. Male admissions 1183; of these 20 were general paralytics, so that the percentage of paralyti male admissions is 17·3. Female admissions 1236; of thes 31 were general paralytics, so that the percentage c paralytic females is 2·5. So that general paralysis is seve times as frequent in males as compared with females i West-end parishes north of the Thames.

North of the Thames—East-end parishes. Total population equals 1.282,911. Male admissions 930; of these 12 were paralytics. so that the percentage of paralytic mal admissions is 13·2, against 17·3 in the West-end parishe north of the Thames. Female admissions 981; of these 3 were general paralytics, so that the percentage is 3·4 i eastern parishes north of the Thames, against 2·5 per cent in the West-end.

In West-end parishes north of the Thames we will fin that 1·75 per 1000 residents were admitted in the two year and of these 9 7 per cent. were general paralytics. I East-end parishes north of the Thames 1·49 per 1000 wer admitted in the two years, and of these 8·2 per cent. wer general paralytics.

In West-end parishes south of the Thames th results obtained are somewhat different, for bot males and females have a higher percentage o general paralytics in the western parishes however, this quite accords with the character of the population in Wandsworth and Lambeth.

In the western parishes the total population is 777,321. The male admissions are 537; of these, 97 are paralytics, a percentage of 18 3. The female admissions are 641; of these, 20 are general paralytics, percentage 3·1. Both male and female incidence of paralysis are high.

In the eastern parishes the total population is 1,066,989 The male admissions are 741; of these, 102 are paralytics a percentage of 13 7 The female admissions are 825; of these, 23 are paralytics, a percentage of 2 7.

The western parishes are higher in both male and female paralytics; in the former 10 per cent of the total admissions are paralytics, to 7·9 per cent in the latter.

These facts entirely agree with what we know of the incidence of general paralysis in the two sexes from practice—viz., the lower we go in the social scale the more common becomes this disease in the female sex; whereas general paralysis is common to all grades of society in the male sex, it is very rare in the better and respectable classes of females in all grades of society. Probably these statistics give a rough idea of the relative prevalence of syphilis in the two sexes.

We may conclude, therefore, that syphilis is commoner in the West-end among males and in the poor East-end among females. Seeing that a very considerable number of paralytics in the West-end do not come into the county asylums it may be assumed that the ratio of six males to one female is well under the mark.

Plague Rats at Seattle.—Seattle, the largest port on Puget Sound, the northernmost of the large ports on the Pacific seaboard of the United States, has found plague rats and is now anxious about possible danger. At this point it becomes at once clear what a strength their public health service is to the United States Instead of anxiously advertising for casual doctors to assist them, they get an additional officer of the service detailed from San Francisco for duty at Seattle, and have many others, experts at this particular work, to help them if required. No plague rats have been so far observed in the neighbouring British Columbian ports, Victoria (60 miles away), and Vancouver (100 miles north), but the Seattle papers are tartly suggesting that that is perhaps only because they have not been looked for, and that the quarantine suggested against ships from Seattle is unnecessary.

GONORRHŒA PHYLACOGEN:

REPORT ON AN INVESTIGATION INTO ITS VALUE IN THE TREATMENT OF SOME GONOCOCCAL INFECTIONS.

By L. W. HARRISON, M.B. Glasg.,
MAJOR, ROYAL ARMY MEDICAL CORPS.

For the opportunity of making this investigation I am indebted to the Editor of THE LANCET, who suggested it and provided me with a supply of the remedy.

Phylacogen is the trade name applied to a series of solutions of bacterial products prepared according to the directions of Dr. A. F. Schafer (California), their inventor. Dr. Schafer's theory is that every bacterial disease is due to mixed infection. The micro-organism to which the disease is usually attributed may preponderate, but others which are commonly found in the body play some part in producing the symptoms which the patient displays. Accordingly, the attack must be directed not only against the specific germ but also against a host of others which assist or are assisted by it. According to a handbook issued by the firm responsible for its manufacture, a basic phylacogen is prepared by mixing together filtrates (through porcelain) of cultures of "staphylococcus pyogenes (albus, aureus, and citreus), streptococcus pyogenes, bacillus pyocyaneus, diplococcus pneumoniæ, bacillus typhosus, bacillus coli communis, bacillus diphtheriæ, streptococcus rheumaticus, and streptococcus erysipelatis." This mixture constitutes "mixed infection phylacogen" and enters into the constitution of each of the specific phylacogens (erysipelas, gonorrhœa, pneumonia, and rheumatism). Each of these is prepared by mixing together equal parts of "mixed infection phylacogen" and the filtrate of a pure culture of the specific micro-organism. It will be realised, therefore, that phylacogens are not exactly vaccines in the commonly accepted sense of the word, since they contain no solid bacteria. They are more analogous to the toxins which are used for the manufacture of antitoxins. It is not intended here to discuss Dr. Schafer's theory, but to relate the results of a short experience of gonorrhœa phylacogen and to offer some comments on the progress of the patients who were treated with this remedy as contrasted with that of similar cases treated by ordinary methods. It is necessary first, however, to make a few remarks on the administration of gonorrhœa phylacogen and on its side-effects.

Methods of Administration and Dosage.

According to the recommendations issued by the makers, gonorrhœa phylacogen may be administered subcutaneously or intravenously, the *former* for choice, and always for the initial dose. The intramuscular method is not recommended, but the reason for this is not stated, nor is it quite clear, unless *it is for reasons of safety. In the* series of cases related below I employed the intramuscular as well as [illegible] and intravenous methods an[illegible] the therapeutic *effect of the* [illegible] was in no way superior to the intramuscular, the local reaction which followed the intramuscular injection was more bearable than that which followed the subcutaneous, especially when large doses were employed.

With regard to dosage, for subcutaneous injection the original recommendation was to commence with 3–5 c.c. and increase to 10, 15, or even 20 c.c., but in a later pamphlet the makers now recommend smaller doses than this—1 or 2 c.c. at first, increasing each dose by 1 or 2 c.c. till a maximum of 10 c.c. is reached. For intravenous injection it is now recommended to commence with 0·125 c.c. to 0·25 c.c., increase very gradually till a dose of 1 c.c. is reached, and thereafter by increments of 1 c.c. to a maximum of 5 c.c., avoiding if possible any marked constitutional reaction. The interval which is recommended between doses is 24 hours or less unless a marked reaction follows the injection, when it may be prolonged to a maximum of 48 hours. A longer interval is deprecated on account of the likelihood of relapse, and for the same reason it is urged that the injections be prolonged till at least 10 days after the patient is relieved of his symptoms.

I have endeavoured to follow these directions as closely as circumstances would allow, but for obvious reasons have not felt justified in prolonging the treatment in cases where it was clear that the remedy was having no effect on the disease. As will be mentioned, the reaction after an injection of gonorrhœa phylacogen is often distinctly unpleasant, and it is not justifiable to repeat this indefinitely when there appears to be no hope of compensatory benefit.

Reaction following Injections of Gonorrhœa Phylacogen.

After subcutaneous, and to a less extent after intramuscular, injection, the site of the injection becomes distinctly painful, the discomfort depending largely on the size of the dose and to a certain extent on the patient. Frequently it lasts well into the following day and may deprive the patient of his sleep. The general symptoms depend on the size of the dose, the patient, and the method of administration. As a general rule, intravenous injections are followed by more constitutional disturbance than intramuscular or subcutaneous. Within an hour or two of the injection there is generally a feeling of chill, and, especially after the first few intravenous injections, this may increase to a definite rigor. The temperature rises to a variable height by the same evening. Generally it reaches 100° to 101° F., but in some of my cases it rose to 104°, and in one case an intramuscular injection of 10 c.c. was followed by a temperature of 105·6°. Most of my patients who received intravenous injections suffered from headache, which was often so severe as to make them prefer the pain following an intramuscular or subcutaneous injection. The majority of patients seem to develop some tolerance to the remedy, the reaction following later not being so severe as after the initial doses.

I have treated with gonorrhœa phylacogen 16 cases, including 1 case of gonococcal arthritis and 10 of epididymitis, and the history of each of these is briefly related below. In cases where it was not contra-indicated patients suffering from urethritis received appropriate local treatment in addition. To avoid unnecessary repetition, by "phylacogen" is meant "gonorrhœa phylacogen" in the following case reports.

CASE 1.—Gonococcal arthritis two days, with very severe pain in the left hip, both knees and both ankles. Moderate swelling of visible joints. Purulent urethral discharge containing fairly numerous gonococci. Intramuscular injection of phylacogen 3 c.c. was followed on the next day by considerable relief of pain in all joints. During the succeeding four days intravenous injections of 1 c.c., 2 c.c., 3 c.c., and 4 c.c. Stiffness and pain completely disappeared and the joints became less swollen; urethral discharge containing gonococci in fair numbers persisted. Five days later return of pain and swelling in the right ankle. Seven intravenous injections of 3 c.c. phylacogen on successive days, during which pain disappeared from ankle, but the right wrist became affected on the second day and the left knee on the seventh day. Intramuscular injection of 10 c.c. phylacogen was followed by relief of all pain. Subsequent progress towards recovery was uneventful.

The history of this case, unfortunately the only one of gonococcal arthritis which I have had an opportunity of treating with phylacogen, appears to support those published by others in testifying to the good effect of phylacogen on gonococcal arthritis.

CASE 2.—Gonorrhœa 8 weeks; epididymitis 1 week. Testicle considerably swollen and rather tender, but no marked pain. Intramuscular injection of 3 c.c. phylacogen. Testicle on following day more painful. Seven intravenous injections of phylacogen during the following 13 days in doses rising from 1 c.c. by increments of 1 c.c. to a maximum of 3 c.c., the injections being generally on alternate days on account of the severity of the reactions. Swelling gradually abated but returned with slight pain on the day after the last of these injections. Intramuscular injection of 10 c.c. phylacogen was followed by relief of all pain. The patient was discharged from hospital a week later for special reasons, the testicle being then about twice the normal size but free from discomfort.

CASE 3.—Gonorrhœa 2 years, with frequent relapses of acute urethritis. Epididymitis 3 days, with severe pain and swelling. Intramuscular injections of 10 c.c., 15 c.c., and 20 c.c. phylacogen during first four days; the testicle became slightly smaller and more comfortable. Intramuscular injection of 20 c.c. phylacogen two days later and six subcutaneous injections of 5 c.c. phylacogen on successive days. Progress much the same as in similar cases treated without vaccine. Urethral discharge continued, with fairly numerous gonococci.

CASE 4.—Gonorrhœa 21 days; epididymitis one day. Five subcutaneous injections of phylacogen in doses increasing from 1 c.c. to 4 c.c. on alternate days. Local and general reaction after each injection fairly severe. Progress apparently uninfluenced by phylacogen.

CASE 5.—Epididymitis one day, with considerable pain and swelling. Intramuscular injection of 5 c.c. phylacogen followed by four intravenous injections on successive days and in doses increasing from 1 c.c. to 3 c.c. Each injection followed by severe reaction. No improvement. Two days later intramuscular injection of 15 c.c. phylacogen was followed by considerable relief of pain. Dose repeated two days later, but two days after this severe relapse of pain and swelling. Phylacogen discontinued and polyvalent stock vaccine commenced in weekly doses. This was followed by steady improvement and there was no further relapse. In this case a large dose of phylacogen seems to have relieved pain, but steady administration of the remedy failed to prevent a severe relapse.

CASE 6.—Gonorrhœa 21 days; epididymitis 4 days. Epididymis moderately swollen, rather tender, but not very painful. Three intramuscular injections of 10 c.c. phylacogen on alternate days, each injection being followed by severe reaction. Testicle on the fifth day not so tender. From the seventh to the thirteenth day of phylacogen treatment six subcutaneous injections of phylacogen, commencing with 1 c.c. and increasing by 1 c.c. to a maximum of 5 c.c. Relapse of pain and swelling on the thirteenth day. Subcutaneous injections continued on fourteenth and fifteenth days. Testicle became more comfortable, but remained considerably enlarged. Urine on the fifteenth day showed numerous threads containing gonococci.

CASE 7.—Gonorrhœa 6 weeks; epididymitis 2 days, with considerable pain in vas deferens. Had previously suffered from metastatic gonococcal conjunctivitis, which cleared up under ordinary vaccine treatment. Intramuscular injections of 4 c.c., 5 c.c., 6 c.c., and 8 c.c. phylacogen on first four days. Pain in the vas disappeared after first injection, but returned on the fifth day, with increase of pain in the epididymis. Intramuscular injections of 10 c.c. phylacogen on the sixth and eighth days were followed by great relief of pain. After five intravenous injections of 1 c.c. to 3 c.c. phylacogen during the succeeding week epididymis was free from pain, but about twice its normal size.

CASE 8.—Gonorrhœa three months. One month after infection commenced very severe epididymitis, which was treated with vaccine and puncture of the epididymis. Testicle had become practically normal, but phylacogen treatment was commenced on account of slight return of pain and swelling, threatening a relapse of epididymitis, and to observe its effect on persistent gleet. Intramuscular injection of 2 c.c. phylacogen was followed by disappearance of pain. Two days later intramuscular injection of 5 c.c. phylacogen, and during the following week five intravenous injections in doses rising by increments of 1 c.c. to a maximum of 3 c.c. At the end of this time a small nodule remained in the epididymis and gleet persisted, with gonococci as numerous in the discharge as before commencing injections with phylacogen.

CASE 9.—[illegible] Epididymis [illegible] enlarged. [illegible] cogen given [illegible] resolution of the epididymitis. Intramuscular injection of 5 c.c. phylacogen followed by three intravenous injections of 1 c.c. to 3 c.c., and then an intramuscular injection of 15 c.c. phylacogen. No apparent effect on gleet or epididymis.

CASE 10.—Gonorrhœa 5 weeks; epididymitis 3 weeks. Epididymis no longer painful, but hard and generally enlarged. Phylacogen given to test its effect in hastening resolution. Subcutaneous injections of 3·5 c.c. and 5 c.c., intramuscular injections of 6 c.c., 8 c.c., 10 c.c. and 10 c.c. on first, second, third [illegible] Five intravenous injections [illegible] five days. Progress towards [illegible] treated on ordinary lines.

CASE 11.—Gonorrhœa 18 months, with interval of freedom from symptoms for 12 months. Epididymitis 2 months, with muco-purulent discharge containing numerous gonococci. On commencement of phylacogen treatment epididymis slightly enlarged, but free from pain and tenderness. Urethral discharge persistent. Eight intramuscular injections of phylacogen on alternate days, commencing with 5 c.c. and increasing steadily to 20 c.c. No apparent effect on urethral discharge or in hastening resolution of epididymitis.

CASE 12.—Gonorrhœa 5 weeks. Gleet, with fairly numerous gonococci in discharge. Intramuscular injections of 3 c.c., 4 c.c., and 5 c.c. phylacogen on successive days; five intravenous injections, increasing from 0·5 c.c. to 3 c.c. during the following week, each of these being followed by marked reaction with severe headache. An attack of influenza then intervened and phylacogen was discontinued for a week. On resumption of phylacogen discharge still persisted, but disappeared after two further intravenous injections of 3 c.c. The disappearance of the discharge in this case may possibly have been due to the phylacogen, but sudden disappearance of urethral discharge at this stage of the disease is fairly common in cases treated by other methods.

CASE 13.—Gonorrhœa 3 weeks. Para-urethral abscess 1 cm. behind the glans penis 2 weeks. During this time the swelling had decreased from about the size of a butter-bean to that of a pea. [illegible] fairly numerous gonococci. [illegible] c.c. and 4 c.c. and eight [illegible] to 3 c.c. phylacogen on successive days. At the end of this time the swelling was of the size of a grape seed, and the discharge was still present, with gonococci in approximately the same numbers as before commencing phylacogen treatment.

CASE 14.—Gonorrhœa 6 months. Slight urethral discharge containing scanty gonococci (about one pair in ten fields). Ten subcutaneous injections of phylacogen in doses increasing gradually from 1 c.c. to 5 c.c. on successive days, the larger doses being followed by severe local reaction. Discharge and numbers of gonococci apparently unaffected.

CASE 15 [illegible] the penis, with consi[illegible] Intramuscular [illegible] ction of 2 c.c. phylacogen on successive days were followed by no relief. Hot sitz baths were ordered. Pain was considerably easier on the third [illegible] venous injections o[illegible] fourth days, by wh[illegible] appeared. Return of pain and swelling on the sixth day. Intramuscular injection of 10 c.c. phylacogen was followed by disappearance of pain. Urethral discharge continued unabated, with numerous gonococci. No phylacogen administered from the eighth to the fourteenth days, by which time discharge had become rather more profuse. Intramuscular injection of 10 c.c. phylacogen was given on the fourteenth day, followed by nine subcutaneous injections of 3 c.c. At the end of this time signs of abscess of the left lobe of prostate showed themselves in severe pain on micturition and a rapid rise of temperature to 104° F., and on the following day there was considerable pain in the right thigh and knee. Phylacogen treatment was discontinued as small doses had failed to avert the complications mentioned, and the patient was too unhappy to risk the addition of the severe reactions which follow larger doses of phylacogen. Ionisation of the thigh and knee with salicylic ions was followed by immediate relief of pain there, and four days later the prostatic abscess burst into the urethra.

CASE 16.—Gonorrhœa 2 weeks; acute prostatitis 4 days, with very severe pain and no sleep for two nights. Intramuscular injection of 5 c.c. phylacogen was followed by complete relief of all pain. At the same time the urine became loaded with pus. Phylacogen continued for one week with daily intramuscular injections in doses increasing to 10 c.c. It was then omitted for one week, at the end of which time the prostatic pain returned. An intramuscular injection of 10 c.c. phylacogen was again followed by complete relief of the pain. Subsequent progress uneventful.

It would appear from the above cases that in my hands phylacogen has been chiefly successful in relieving pain, and this was especially marked in the case of gonococcal arthritis. In this case also it appears to have hastened recovery, but the same cannot be said for its effect on urethritis and epididymitis, and I have not been able to convince myself that it has any particular therapeutic value in these forms of gonococcal infection. Possibly my lack of success has been due to errors in the administration of phylacogen. If so, I can only hope that others, profiting by my mistakes, may achieve greater success. As far as can be judged from such a limited experience, the effect of phylacogen in relieving pain seems to be more marked after large than small doses, and it is possible that this is because the former are followed by more febrile reaction, which, temporarily at any rate, inhibits the activity of the gonococcus.

I have made a large number of tests to ascertain whether the blood serum of patients suffering from gonococcal infections deviates complement in the presence of phylacogen as antigen, but by a method which is sufficiently delicate to demonstrate antibodies to ordinary gonococcal antigen in most cases of ordinary gonorrhœa I have failed to demonstrate antibody to phylacogen. Possibly this is because phylacogen contains antigen in such a weak dilution that it cannot be used as antigen in a complement deviation test. The presence of phenol in the commercial product puts a limit on the amount of it which can be used in a complement-deviation test, and it would be interesting to test it after concentration and in the absence of phenol.

RADCLIFFE INFIRMARY, OXFORD.—The Chancellor of the University of Oxford, Lord Curzon of Kedleston, will open the new buildings of the Radcliffe Infirmary on Wednesday afternoon, Nov. 26th, at 2.30 o'clock, after luncheon in the hall of Queen's College.

REPORT AND REMARKS ON A SMALL EPIDEMIC OF POLIOMYELITIS,

OCCURRING IN THE PRACTICE OF G. H. JONES, M.R.C.S. ENG., L.R.C.P. LOND., AND G. M. W. HODGES, M.B., B.S. LOND., OF DEDDINGTON, OXON.[1]

BY PAUL B. ROTH, F.R.C.S. ENG.,

SURGEON, KENSINGTON AND FULHAM GENERAL HOSPITAL; SENIOR ORTHOPÆDIC CLINICAL ASSISTANT, LONDON HOSPITAL.

THIS epidemic consisted of six cases,[2] which occurred in five small villages around Deddington between August 9th and Sept. 15th, 1911. There was no death.

The sex, age, and order of attack of the cases are best shown in the following table:—

Case.	Age.	Sex.	Date of Onset.
1	8½ years	Boy	August 9th
2	1 10/12 ,, ...	,, ...	,, 13th.
3	9/12 year	,, ...	,, 16th.
4	4 years	Girl	,, 17th.
5	1 year	Boy	Sept. 11th.
6	10/12 ,, ...	,, ...	,, 15th.

Nature of onset.—Case 1: Occipital headache, head retraction and vomiting, temperature 103·2° F. Cases 2 and 3: Fever and vomiting. Case 4: Fever, headache, and vomiting. Case 5: Fever and drowsiness, temperature 101·4°, and according to mother headache. Case 6: Fever and restlessness, temperature 103–105°, and according to mother headache. Cases 1 and 6 may be regarded as severe cases, the others as slight ones. In all except one the acute symptoms lasted 2–4 days, and were then followed by pain and paresis; the pain in the affected limbs was a marked feature. As the pain and paresis developed the acute symptoms gradually subsided. In Case 6 there was pain for 6 days, and temperature 103–105°, after the appearance of paralysis. In Case 1 there was an unusual symptom, urinary retention.

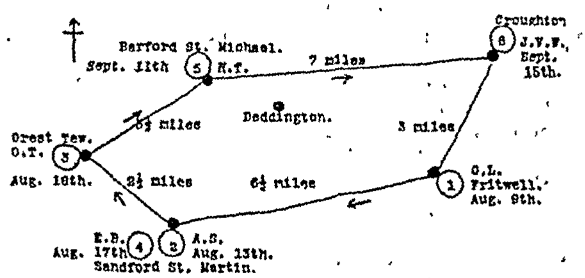
Parts affected.—Case 1: Both legs, right shoulder, arm, and forearm. Case 2: Both legs. Case 3: Both legs and perhaps erectores spinæ. Case 4: Left leg, both forearms, right side of face, right external rectus causing internal strabismus. Case 5: Right shoulder muscles and sterno-mastoid causing typical wryneck. Case 6: Both legs and erectores spinæ.

Recovery (as observed in July, 1913).—Case 1: The right leg recovered to some extent, the shoulder girdle, arm, and left leg remaining the same. Case 2: Made an excellent recovery, but there is a fair amount of wasting in the left thigh. Case 3: Now has only slight foot-drop in one foot. Case 4: Made a perfect recovery with the exception of the face, in which, however, she lost the strabismus. Case 5: The sterno-mastoid recovered, but the shoulder muscles remain paralysed. Case 6: Made a good recovery; now "tends to trip with left foot owing to the slight foot-drop."

Remarks on the mode of infection.—The question of how the infection could have been conveyed in this epidemic is of interest.

Dr. Hodges says: "The cases were somewhat widely scattered, only Case 4 and Case 2 occurring in the same village, and these two lived under entirely different conditions and had never met. They were attacked only four days apart. It is certain none of the cases met each other before their attacks either at school or at school treats, nor had their parents met. The half-sister of Case 2, however, attended the same school as the family of Case 4." Dr. Hodges has made a rough diagram, which I have slightly altered (Fig. 1), to demonstrate the distances between the cases. A glance at it at once shows (1) the impossibility of direct infection in these cases; and (2) that the cases were affected one after the other in a circular manner.

FIG. 1.



Sketch map showing distribution of cases. The black dots indicate villages.

In one of his letters to me Dr. Hodges wrote: "*The only point in their environment which is the same in all cases is the close proximity of stables.*" Thus in Case 1 there is a cattle-yard immediately behind the house; Case 2 lives in a lodge by the stable-yard of S—— Park; Case 3's father is a farmer; Case 4's father is a farm labourer; Case 5's father is a blacksmith; and Case 6 lives in a cottage with a stable immediately behind it.

That this environment may be of extreme importance is shown by the work of Dr. Milton J. Rosenau, of Harvard Medical School, whose experiments have been confirmed by John F. Anderson and Wade H. Frost.[3] They say:—

> To summarise, three monkeys exposed daily to the bites of several hundred Stomoxys, which at the same time were allowed daily to bite two monkeys suffering from poliomyelitis caused by intracerebral inoculation, developed quite typical symptoms of poliomyelitis eight, seven, and nine days respectively from the date of their first exposure.

That is to say, they demonstrate conclusively that poliomyelitis can be transmitted from monkey to monkey through the agency of this fly. On inquiry I find that the fly Stomoxys calcitrans is also found in large numbers in this country, and in most inhabited parts of the world, tropical as well as temperate. Mr. Ernest E. Austen, of the British Museum (Natural History) writes[4]:—

> (Stomoxys calcitrans)—a species often met with even in the centres of large towns, though commoner in the suburbs and found almost everywhere in the country[5]—is a blood-sucking fly which is sometimes mistaken for Musca domestica (the house-fly), with the result that the house-fly is occasionally alleged to have inflicted a bite, although its proboscis is merely adapted for sucking and is quite incapable of piercing the skin. Though agreeing with the house-fly in length, Stomoxys calcitrans is of a somewhat broader and more thick-set shape (see Fig. 2), and may readily be

---

[1] A paper read before the Orthopædic Subsection of the Royal Society of Medicine.

[2] Dr. Hodges writes: "At the time of this little epidemic there was to the best of my recollection and as far as I can gather from case-notes, no case of "influenza" in our practice. Another curious point was that we seemed to have a monopoly of poliomyelitis, none of the three other practitioners covering the district having a case."

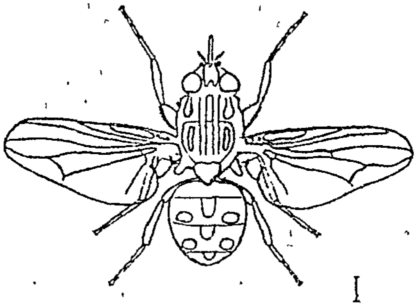
[4] The House-fly as a Danger to Health, 1913.

[5] The geographical ran[illegible] yet been fully elucidated, but it is [illegible] is generally distributed in Euro[illegible] North America, where it is said to be very comm[illegible] A race of it is found in the Gambia Colony, West Africa, and it has also been recorded as occurring in Hong-Kong, Batavia (Java), Ceylon, and Sydney (New South Wales). A specimen from the Naini Tal District, in Northern I[illegible] British Blood-Suckin[illegible]

distinguished from Musca domestica (see Fig. 3) by the character of its proboscis, which is rigid and slender, and is always visible, projecting like an awl horizontally in front of the head. (Moreover) the fourth longitudinal vein in the wing of this fly, although somewhat bent up at the end, is not sharply elbowed as in the house-fly.

These flies breed in decaying vegetable matter, are found about stables and cowsheds, and are frequently to be seen in large numbers resting on gates and rails and fences. They are most prevalent in August and September. They attack human beings as well as horses and cattle.[6] The bite is a minute puncture inflicted by the proboscis.

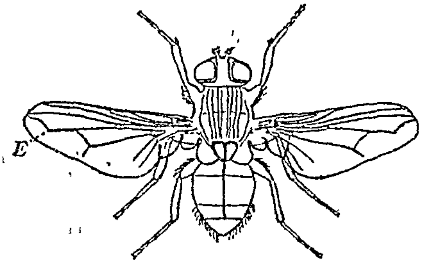
FIG. 2



Sketch of stomoxys calcitrans (female). From "The House Fly," C. Gordon Hewitt. 1910.

Before giving any opinion on this matter there is one fact to which I must refer—the recent discovery at a place named Borna, near Leipzig, of a disease in horses which seems closely allied to poliomyelitis. This has been named the "Bornasche Krankheit"[7]; a similar disease in horses has also been described in other parts of Germany.

FIG. 3.



Sketch of house fly, musca domestica (female). F, elbow. From "The House Fly," C. Gordon Hewitt. 1910.

Conclusions.—The points to which I wish to direct attention are: 1. "That the infective material (in the laboratory) is very resistant to cold and the disease much more common in warm weather, and yet that the epidemics stop as soon as the cooler weather comes, would suggest that the infection is carried by some insect that is killed or disappears as soon as the summer ends."[8] 2. It has been proved that the disease can be transmitted from an infected monkey to a healthy monkey by the bites of the flies Stomoxys calcitrans. 3. These flies are found in all countries where epidemics of poliomyelitis have been described as occurring. 4. A favourite habitat of the flies is stables and cowsheds. 5. These flies bite horses and cattle and human beings. 6. A disease similar to poliomyelitis occurs in horses. 7. In the epidemic here reported the infection could not possibly have been direct. 8. There were *stables or cattle-yards* very close to the houses of the children affected.

From a consideration of these points I suggest that this epidemic was originated by infected Stomoxys biting Case 1 in the cattle-yard at Fritwell; that the infected patient was bitten by other Stomoxys which in turn became infected and were carried by horses or cattle, or on carts and wagons,[9] to the stableyard at Sandford St. Martin, where two more children were bitten and became infected, and so on through the other three villages. If this theory—viz., the transmission of poliomyelitis by the Stomoxys—should prove to be correct, not only for this particular epidemic, but for all other epidemics of poliomyelitis, then it should be possible, by a wholesale crusade against this species of fly, to banish the disease from large regions of the globe.

Notes of Cases.

CASE 1.—Male, aged 8½ years, father a farm bailiff, cattle-yard immediately behind house. Onset on August 9th, 1911; taken ill with severe occipital headache, head retraction, and vomiting; temperature 103·2° F. On the 11th the vomiting ceased and the headache was less, when there appeared weakness of both legs with much pain, both knee-jerks were lost, the right plantar reflex was flexor, and the left was absent. Kernig's sign was not present. Temperature 101·6°. On the 13th the boy was very ill. There was constant pain in both legs and the right shoulder, which had now become involved. The muscles chiefly affected appeared to be the extensor group of the thigh and the peroneal in the lower limbs, and the deltoid in the shoulder. Temperature 100·8°. There were retention of urine (catheter passed twice) and obstinate constipation only relieved by enemata. On the 15th the temperature was normal and the pain less; urine was passed naturally, and the bowels were opened with aperients. After-history: The boy gradually improved. In November the following muscles showed the reaction of degeneration—deltoid, coraco-brachialis, biceps, brachialis anticus, triceps, extensor carpi radialis, longior or brevior, in right upper extremity; hamstrings, quadriceps, adductors, tibialis anticus, and gastrocnemius in left lower extremity. He went to the Orthopædic Hospital at Birmingham, with the result that the right leg recovered to some extent, the shoulder girdle, arm, and left leg remaining the same.

CASE 2.—Male, aged 22 months, father a gardener, lives in a lodge by the stable yard of S—— Park. Onset on August 13th, 1911, with fever and vomiting. The child was first seen on the 18th, when there were paresis and pain in both legs, the muscles chiefly affected being the hamstrings on both sides and quadriceps of left thigh. The knee-jerks were absent, the right plantar reflex was doubtful, and the left extensor. After-history: The patient gradually made an excellent recovery, and he now walks well, but there is a fair amount of wasting in the left thigh.

CASE 3.—Male, aged 9 months, father is a farmer. Onset on August 16th, 1911, with fever and vomiting. On the

[illegible] Austen, loc. cit., 3.

18th there were pain and paresis of the quadriceps and hamstrings of both thighs. The knee-jerks were unobtainable; the extensors of the spine were probably involved. After-history: The patient gradually recovered, and now the left leg is half an inch shorter than the right, and there is slight foot-drop.

Case 4.—Female, aged 4 years, father a farm labourer. Onset on August 17th, 1911, with fever, headache, and vomiting. On the 23rd she was first seen; she complained of pain in both forearms. There was paresis of the extensors of both wrists with double wrist-drop. Very marked right facial paralysis was also present, the orbicularis palpebrarum and muscles of the mouth being especially affected. There was some weakness of the left leg, but no pain. The right knee-jerk was normal and the left diminished; the right plantar reflex was flexor and the left extensor. Temperature 99·4° F. On the 26th right internal strabismus developed. On the 30th the left plantar reflex was flexor, but was obtained with difficulty. After-history: The girl gradually made a perfect recovery with the exception of the face, in which, however, the strabismus was lost.

Case 5.—Male, aged 1 year, father a blacksmith. Onset on Sept. 11th, 1911, with fever and drowsiness, and the mother says headache. On the 14th the infant was first seen. There were pain and paresis of the right shoulder; the deltoid and sterno-mastoid appeared chiefly involved with typical wryneck. Temperature 101·4° F. After-history: The sterno-mastoid quickly recovered, but there remains paralysis of the deltoid, supra- and infra-spinatus, subscapularis, the upper part of the trapezius, and the coraco-brachialis.

Case 6.—Male aged 10 months; stable immediately behind the cottage. Onset on Sept. 15th, 1911, with restlessness and fever, and the mother says headache. On the 18th, when the child was first seen, the hamstrings and quadriceps of both thighs were involved with much pain and also the erector spinæ. The pain was too severe to be sure of the knee-jerks. Temperature 104·2° F. The pain was very marked for the next six days, and the temperature remained at 103°–105°. After-history: Eventually the patient made a good recovery and now walks well, but tends to trip with the left foot owing to slight foot-drop. There is some slight wasting of the extensors and adductors of the thigh and the peronei of the leg on the left side.

I am much indebted to Mr. Jones and Dr. Hodges for permission to publish their cases, and to Mr. Austen for valuable assistance in the preparation of this paper.

Harley-street, W.

NOTES OF AN

OUTBREAK OF ACUTE ANTERIOR POLIOMYELITIS AT WEST KIRBY.

By GEORGE JUBB, M.D. Glasg., D.P.H. Oxon.,
ASSISTANT MEDICAL OFFICER, CHESHIRE COUNTY COUNCIL.

The following cases of acute anterior poliomyelitis were discovered in West Kirby in 1912 and 1913, and as they present some remarkable features in their occurrence it was considered possible that their publication might be of general interest. I am indebted to Dr. J. B. Yeoman, medical officer of health for North-West Cheshire, for his kindness in giving me facilities for investigating the outbreak and permission to publish the results.

West Kirby is an urban district with about 6000 inhabitants, and it is a favourite seaside resort. It occupies a sheltered position at the north-west corner of the Wirral Peninsula. Its sanitary condition is good, it is well paved and well drained, there are a good water-supply, a water-carriage system of sewage removal, and efficient cleansing, dust being removed in covered bins, and there was found no evidence of undue accumulation of manure or other nuisance. Strict inquiries have been made, and no history can be obtained of any case of infantile paralysis having happened in the district prior to the present outbreak, the first case of which occurred on July 11th, 1912. The only antecedent condition which may possibly have some bearing on the origin of the infection was the arrival of a donkey in a verminous condition at the home of the first case. I append a brief history of the cases.

Case 1.—Male aged 6 years. The illness began on July 11th, 1912, with sickness and pains in the legs. He was treated for rheumatism for a week, and then paralysis of the left leg was discovered. His brother, 5 years old, slept with him till the illness began. Three weeks before the boy's illness his father bought a donkey from Ireland for the children. When the donkey arrived the boy, his brother, and a cousin of the same age immediately climbed on its back and in consequence got a great number of lice on their clothes, as the extremely verminous condition of the animal had escaped notice. Their clothes had to be taken off and washed, and the donkey was clipped and cleansed; it was afterwards kept for three months in a field behind the house. The boy has been away from the district from the middle of May to Sept. 25th, 1913. His grandmother has a baker's shop in the same road.

Case 2.—Female aged 2½ years. The illness began on July 6th, 1913, with headache. A medical man was sent for on the 8th, as she was delirious. Paralysis was discovered on the 10th, both hands and feet being affected; now the feet only are paralysed. This case is about 100 yards from Case 1, and the parents have a bread, cooked meat, and chipped potato business on the premises. Cases 3, 4, and 5 are customers and live quite near. There is also a connexion between Case 1 and Case 2, as the parents of Case 2 frequently get bread and yeast from the baker's shop associated with Case 1. There are other children aged 15, 13, 11, and 8 years in the house, in which there has been scarlet fever during last summer.

Case 3.—Female aged 5 years. The illness began on July 28th, 1913, with sickness and vomiting. The child was able to go out on the 28th and 29th, but paralysis occurred on the 30th. This child went to the Presbyterian Sunday School, and its parents were customers of the shop associated with Case 2. Other children are aged 13, 9, and 6 years. There was scarlet fever in the house this summer.

Case 4.—Male aged 1 year and 3 months. The illness began on August 1st, 1913, with drowsiness; on the 2nd there was headache. The child was ill for a week, and then a medical man was called in and diagnosed bronchopneumonia. At the end of another week it was discovered that there was paralysis of the legs. The other children are aged 13, 12, 9, 5, and 3 years, and go to the Presbyterian Sunday School. The parents are customers of the shop associated with Case 2.

Case 5.—Female aged 1 year and 9 months. The illness began on August 14th, 1913; the child cried all day. Paralysis was discovered on the 17th. There are no other children. The parents are customers of the shop associated with Case 2. The child was taken to see the patient in Case 3 on August 2nd when this girl was ill.

Case 6.—Female aged 6 years. The illness began on August 3rd, 1913. On the 4th she had pains in her head and dragged her left foot. On the 7th and 8th she complained of pains in her neck and legs. Both legs were paralysed and the right arm partially. On the 9th she went to a children's hospital. This case occurred about a mile from the previous cases, but in the immediate neighbourhood there are three shops (a baker's, a dairy, and a cooked meat shop) occupied by relatives of the proprietor of the cooked meat shop associated with Case 2. The dairy gets bread from the shop (Case 2) by means of a milk cart and horse. Other children are aged 16, 14, 12, 10, and 8 years. They go to the Presbyterian Sunday School, as do Case 3 and the brothers and sisters of Case 4.

Case 7.—Male aged 1 year. The illness began on August 6th, 1913, with screaming. On the 9th there was a rash on the buttocks. On the 10th the child was unconscious, and there was retraction of the head, the arms being paralysed and the neck stiff. Other children are aged 11, 8, and 6 years. The father cleans the windows of the cooked meat shop mentioned in connexion with the previous case as being in this district. This case is in the next road to Case 6.

CASE 8.—Female aged 4 years. The illness began on August 28th, 1913, with drowsiness, and squinting was noticed on the next day. The mother thought there was slight paralysis of the left leg. The child was in bed a fortnight only, and is now running about, but with a marked squint in the left eye. Other children are aged 14, 11, and 6 years. This case is across the road from the previous case.

I do not intend to enter further on the clinical features of the cases beyond drawing attention to the fact that the meningeal type prevailed. For the purpose of the present article the cases are more interesting from the epidemiological point of view.

It will be seen that there was a primary case in July, 1912, and as far as is known no others followed. During 1913 this primary case has been away from the district for treatment of his paralysis from the middle of May to Sept. 25th. Then there was a primary case in July, 1913, followed by three secondary cases in the same neighbourhood, and other three cases (one tertiary and two quaternary) grouped together about a mile away from the primary and secondary cases. It has been suggested to me that the incidence of these cases closely resembles an outbreak of typhus, and if so it seems reasonable to suspect that the spread of both diseases may be effected by means of the same agents—e.g., lice.

In Case 1 the mother definitely attributes the boy's illness to the arrival of the donkey, which, as has already been mentioned, was infested with lice, and it is interesting to note that in a great proportion of previous outbreaks of poliomyelitis there has been an apparent connexion with domestic animals. Seeing that Case 1 has been absent so long from the district this year it is probable that there was a carrier case which carried on the infection to 1913, and this might have been the younger brother if he had an abortive attack, or there may have been other atypical cases in 1912. According to Netter the serum of sporadic cases of poliomyelitis is active for two years, so that the infectivity of recent cases may be fairly prolonged.

There can be little doubt that Cases 3, 4, and 5 were infected from Case 2, though Case 5 might also have been infected from Case 3, which she visited. The infection *might* have been carried by means of flies, but as it is rather a poor neighbourhood it is just as likely that the infection was carried by means of lice.

Case 6 is the first in the third series, and she goes to a Sunday school in the district of the primary and secondary cases, attended also by Case 3 (who is about the same age) and by the brothers and sisters of Case 4. It seems probable that Case 6 was there infected and brought the infection to the new district. Cases 7 and 8 were probably infected from Case 6. There is, however, a direct communication between the two districts by a milk cart from the dairy near the tertiary case, which carries milk to the first district and brings back bread from the shop associated with Case 2. This would appear to be in favour of the theory of infection being conveyed by flies. It is worthy of notice, too, that with all the cases there was an apparent connexion with shops purveying food, and more especially bread. Their milk-supply was diverse and apparently therefore not concerned.

Transmission of the infective agent in poliomyelitis, whether it is a non-motile protozoon or not, certainly does not seem to be aerial, as in most of the West Kirby cases so many other children, presumably susceptible, were exposed to infection without developing the disease or showing signs of illness. In some of the cases other and younger children slept in the same bed with the patient up to the first day or two of the illness, and two of the cases were at an early stage transferred into different children's hospitals and nursed there, in the absence of any special precautions, without other cases arising. If the infection, then, is conveyed by a biting insect, it appears reasonable to suppose that it might just as easily be conveyed by the louse as by a biting fly, and in view of the suspicions raised regarding this possible mode of infection in the West Kirby cases it would seem desirable to secure and collect further information, where possible, bearing on this question.

Chester.

TWO CASES OF ASCITES TREATED BY MULTIPLE PARACENTESIS AND BY FEMORAL DRAINAGE.

BY W. GIFFORD NASH, F.R.C.S. ENG.,
SURGEON TO THE BEDFORD COUNTY HOSPITAL.

THE two cases of ascites here reported present several points of interest, and may for that reason merit a place in the columns of THE LANCET.

CASE 1. *Ascites treated by paracentesis, omentopexy, and femoral drainage.*—The patient, aged 48, a servant in a public house, was admitted to the Bedford County Hospital on April 29th, 1909, suffering from ascites. She had had two miscarriages at the age of 20, and when about 25 years old she had syphilis, for which she was under treatment for several months. She was then and for several years afterwards a domestic servant. Later she became a barmaid, but denies that she ever drank much alcohol, sometimes going for days without any. Her beverage was stout. For the last seven years she was nearly an abstainer. In 1905 her periods ceased and her abdomen began to swell. Early in 1908 she states that she was in the Samaritan Hospital, London, for three weeks suffering from ascites. Nothing was done. In August of the same year she went into St. Bartholomew's Hospital and was tapped, 14 pints being removed. In January, 1909, at the same hospital 20 pints were drawn off. When she left St. Bartholomew's Hospital she weighed 8 st. in her dressing-gown. She went to her home in Bedfordshire, where on March 26th, 1909, spontaneous rupture occurred at the umbilicus and 30 pints of fluid escaped. The flow continued for a fortnight.

On admission on April 29th, 1909, the abdomen measured 48 inches at the umbilicus. The liver was displaced upwards as high as the fourth rib. There was a soft swelling, 3 inches in diameter, attached to the lower ribs in the mid-axillary line. This was diagnosed as a gumma, and a mixture containing mercury and iodide of potassium was ordered. Paracentesis of the abdomen was performed on the following dates: May 2nd, 1909, 41½ pints; May 23rd, 32 pints; and June 13th, 33 pints. On June 15th the abdomen was opened above the umbilicus and omentopexy performed. There were perihepatitis and perisplenitis. The liver was about the normal size and contained numerous gummata. The spleen was much enlarged and also contained gummata. After this operation the ascites recurred and parencentesis was performed as follows: July 4th, 16 pints; July 25th, 19 pints; August 15th, 18 pints; Sept. 5th, 9 pints; and Sept. 26th, 9 pints. On Sept. 29th she was discharged from hospital and no further medicine was taken.

She returned for paracentesis as follows: Oct. 28th, 1909, 13 pints; Dec. 15th, 14 pints, and on Feb. 18th, 1910, 11 pints. On Feb. 25th a bone bobbin was inserted in the right femoral canal, incisions being made in the middle line of the abdomen and in the femoral region. The wounds healed without any leakage. In all the patient was tapped 14 times and 280 pints of fluid were drawn off.

The patient was examined on March 21st, 1911, exactly a year after leaving the hospital. She looked in excellent health and weighed in her clothes 12 st 2 lb. The swelling on the ribs had disappeared. There was no ascites. The liver could not be felt, but the spleen was considerably enlarged. No trace of the bobbin could be felt. She was seen on Oct. 25th, 1913, when there was no return of ascities. Her spleen was enlarged, her weight 11½ st., her health was excellent, and she was earning her living as a housekeeper and barmaid.

CASE 2. *Cirrhosis of liver; ascites; femoral drainage; recovery.*—The patient, a barman, aged 43, was admitted to the Bedford County Hospital on March 27th, 1912, suffering from ascites. He had enjoyed good health until Christmas, 1911, when he became jaundiced and his legs and abdomen swelled. He was admitted to St. George's Hospital, London, and tapped on the following dates: Jan. 23rd, 1912, 5 pints; Feb 6th, 14 pints; Feb. 20th, 16 pints; March 4th, 12 pints; and March 15th 15 pints There was no ascites when he was admitted to St. George's Hospital, but it developed within a fortnight. He was very ill when he left St. George's and was advised to go to an infirmary.

On admission, under my care, he was jaundiced, the abdomen was much distended, and the legs were swollen He had considerable dyspnœa. He denied any history of syphilis, and no sign of it could be found. On March 27th he was tapped and 30 pints of fluid evacuated. The liver was then felt enlarged to midway between the costal margin and the umbilicus. Small nodules studded its surface, with one large one in the gall-bladder region On April 11th the abdomen was again tapped and 17 pints removed. On the 12th a bone bobbin was inserted in the right femoral canal. Owing to re-accumulation of fluid and to prevent tension on the wound the abdomen was tapped on April 21st and 12 pints drawn off. On May 3rd 11 pints and on the 12th 9 pints were withdrawn. On July 13th he left the hospital. There was then no ascites, the liver was still the same size, and there was slight jaundice. From April 1st until he left the hospital a mixture containing mercury and iodide of potassium was given.

On Oct 27th, 1912, there was still slight jaundice, the liver showed no change, and there was a slight trace of fluid in the abdomen. On Oct. 23rd, 1913, he reported that he was quite well, with no abdominal swelling or jaundice, and that he had returned to work as a barman in the previous July.

In the first of these cases syphilis probably was the main factor in producing the ascites, as there was a distinct history of the disease and the presence of the gumma on the ribs and gummata in the liver and spleen. The occupation of the patient made one suspect alcohol as an additional cause.

In the second case there was no evidence of syphilis except the rather large nodule in the region of the gall-bladder. The occupation and appearance of the man suggested alcoholism. The presence of jaundice and œdema of the legs were also in favour of alcoholic cirrhosis. The fact that the man recovered after repeated tappings and operation is against pure alcoholic cirrhosis, as Rolleston and Hale White[1] are of opinion that such cases seldom survive more than one or, at the most, two tappings. Spontaneous rupture at the umbilicus must be a very rare event, as many authors do not even mention its occurrence.

Alcoholics are such notorious liars that it is very difficult to obtain a history of syphilis, and syphilis may have occurred without leaving any trace behind. It appears to be quite justifiable to try antisyphilitic remedies in any case in which the patient with ascites (due to liver disease) survives two or more tappings. The introduction of a bone bobbin into the femoral canal was originally suggested by Dr. W. Essex Wynter.

Bedford.

POLYVALENT TUBERCULIN AND THE TYPES OF TEMPERATURE REACTION; A NEW TECHNIQUE.

BY HALLIDAY SUTHERLAND, M.D. EDIN.,
FELLOW OF THE ROYAL SOCIETY OF MEDICINE; MEDICAL OFFICER TO THE ST. MARYLEBONE TUBERCULOSIS DISPENSARY.

THE design of tuberculin treatment is to induce in the infected organism a general immunity to the toxins of tuberculin in the hope that this will be associated with a relative immunity to the living tubercle bacillus. Immunity to tuberculin does not always mean immunity to tuberculosis. Theoretically the problem is as follows. If tuberculin were identical with the living tubercle bacillus, how should an organism infected with the latter give an immunising response to the first? Again, if the two were entirely different an immunity to the one would not represent an immunity to the other. Therefore, the more a tuberculin corresponds, without absolute similarity, to the infecting tubercle bacillus the more likely is an immunity to tuberculosis to be attained. The late Professor Arloign, of Lyons, used an attenuated living culture to immunise bovines against a lethal dose of a virulent culture. Webb, of Colorado, has injected small quantities of an attenuated living culture of human tubercle bacilli into children. In general vaccine treatment autogenous vaccines have been found most useful. Tuberculins contain either the exotoxins or the endotoxins of the tubercle bacillus. It is possible that a tuberculin might raise the immunity to the endotoxins without affecting immunity to the exotoxins. All who have worked with tuberculin have obtained excellent results in some cases and indifferent results in others. This might be due to the tuberculin employed not sufficiently approximating in its chemical constitution to the tuberculous toxins in the patient's system. On these grounds I began to use in October, 1911, a polyvalent tuberculin of the following constitution in each cubic centimetre—tuberculin Koch, 0·025 c.c.; bovine tuberculin, 0·025 c.c.; vacuum tuberculin, 0·025 c.c.; bovine vacuum tuberculin, 0·025 c.c.; tuberculin T.R., 0·05 c.c.; bovine tuberculin T.R., 0·05 c.c.; bacillary emulsion, 0·033 c.c.; bovine bacillary emulsion, 0·033 c.c.; polygenous bacillary emulsion, 0·034 c.c.; T.O.A., 0·35 c.c.; and P.T.O.$_v$, 0·35 c.c. (Prepared for me by Messrs. Allen and Hanbury.)

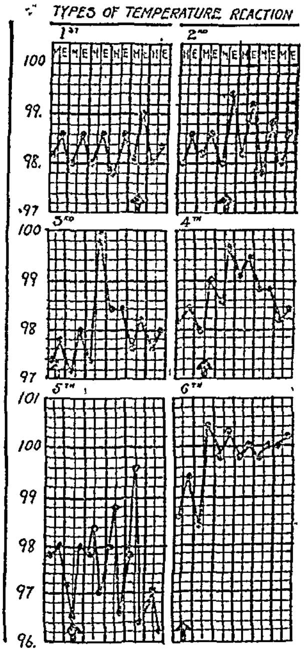
Preparation of dilutions.—Nine dilutions are made from the pure polyvalent tuberculin by measuring 18 c.c. of 0·8 per cent. sterile NaCl solution into sterilised glass-stoppered bottles marked D_1, D_2, D_3, D_4, D_5, D_6, D_7, D_8, and D_9. To the solution marked D_1 add 2 c.c. of pure polyvalent tuberculin and mix well. By adding 2 c.c. of D_1 to the saline solution in the second bottle D_2 is prepared, and so on. Each dilution is thus ten times weaker than its predecessor. The dilutions are made in the cold. With ordinary asepsis they retain their properties for two to three weeks. When the pure tuberculin and its dilutions have stood for some hours the bacterial débris settles as a fine precipitate. If the solution be gently rotated this débris rises like a thin, curling column of white smoke into the supernatant fluid, and forms a perfect emulsion. After two or three weeks the débris in the dilutions will become agglutinated, when fresh dilutions must be prepared. The pure polyvalent tuberculin will retain its properties for several months. Bacterial contamination of the solutions is indicated by small, round, white, fluffy growths or by surface moulds.

Cases suitable for tuberculin.—It is impossible to consider the selection of cases in terms of a purely anatomical classification (Turbans), and the question is best discussed on the basis of a clinical classification such as Philips's. The following groups are suited for tuberculin treatment. The early tuberculous infections of childhood, as represented by L_1 and L_2, are given tuberculin as a prophylactic. In old arrested lesions, indicated by L_3, tuberculin is employed to prevent a relapse. In L_1s and L_2s we have cases where the active onset is recent, systemic intoxication slight; and again, there are the old-standing chronic cases with little systemic disturbance, represented by L_3s. All these do well on tuberculin. By L_1S we mean early local disease with equivalent systemic intoxication, which should be combated by rest in bed, and when the large S has been converted into a small s, tuberculin may be given either at home or at a sanatorium. In the same way L_2S and L_3S may be treated with tuberculin.

Precautions of administration.—The patient must chart his temperature, and is required to record on his chart the pulse rate and the daily amount of sputum. Female patients should draw a black line on the chart during the menses, as the menstrual rise might simulate a reaction. Pregnancy is not a contra-indication, even with a slight degree of albuminuria. The temperature should be taken at 8 A.M., 4 P.M., and 8 P.M. While rectal temperatures are most accurate, it is difficult outside a sanatorium to get ambulant patients to take their temperatures in this way, and in these cases axillary temperatures are more reliable than readings in the mouth. Injections are made with a German Record syringe, platinum iridium needle, graduated to 1/50th c.c. The syringe is washed out before and after each injection with pure ether, and the patient's skin may be wiped with ether. The injections are made subcutaneously on the anterior aspect of the upper arm about the middle of the biceps, where the skin is least sensitive and one is able to avoid veins and nerves.

The principles of dosage.—The dose of tuberculin is gradually increased on the assumption that the more the patient can tolerate with safety the greater is the immunising response. A mechanical dosage is impossible since the optimum dose will depend on the patient's condition, and a dose of tuberculin is large or small, according to its relation to the degree of systemic intoxication. The geometrical progression I have found most serviceable is the quarter, and the ten doses in each solution are 0·13 c.c., 0·16 c.c., 0·2 c.c., 0·25 c.c., 0·32 c.c., 0·4 c.c., 0·5 c.c., 0·63 c.c., 0·79 c.c., and 1 c.c. The injections are given once or twice a week according to the patient's condition, and the initial dose is usually D_6 1 c.c. or D_7 1 c.c. The correct dose will adjust the balance on the side of immunity by the relation of the amount of tuberculin injected to the general condition of the patient, of which the first is under our control, while the second may be measured by clinical methods. The early case of slight severity allows a wide margin for error, and to this I attribute not only the brilliant results of careful treatment, but also the benefit which has occurred in spite of haphazard methods. In advanced disease the conditions are very different. The patient is being poisoned by massive doses of toxin from his own system, and the mechanism of immunity is almost in full abeyance. It is reasonable to presume that the dose of tuberculin should be reduced to meet a lowered vitality, so long as sensitiveness is still present. This may be partly judged by the local reaction, and I have seen a marked local reaction follow an injection of D_{10}1 c.c., polyvalent tuberculin, or 1/10,000,000,000th of a cubic centimetre. In cases of advanced disease with secondary infection these infinitesimal doses may be combined with the administration of an autogenous vaccine.

The types of temperature reaction.—The general reaction to tuberculin includes a group of symptoms referable to the toxic properties of this agent on the neuro-muscular systems. These symptoms are of major clinical importance since they are produced by a smaller dose than will cause a focal reaction. Of the whole group the temperature reaction is the key to successful treatment. None will deny that the failures of the early tuberculin era were due to ignoring temperature reactions. While that is generally admitted, the error continues of referring to reactions as if they differed in degree but not in type. From a failure to differentiate between the types of temperature reaction, two rival schools of the reaction and the reactionless method have arisen. The absolutely incompatible theories, the contradictory published results, the general confusion of thought in the mind of the profession generally, require no recollection. The truth of the matter is that both schools are right. There are some reactions which all may disregard with impunity. There are others which no intelligent physician will dare to overlook. I also suggest that in these types of temperature we have an accurate and scientific indication as to dosage. (See chart.)



Before proceeding to describe these types it is postulated that a rise of temperature, even of half a degree Fahrenheit above the mean, occurring within 72 hours of an injection of tuberculin is to be regarded as a reaction. A rise of temperature reaching its maximum within 24 hours of an injection is an *immediate reaction*, and may occur four hours after the injection. A rise of temperature reaching its maximum within 48 hours of the injection is a *delayed reaction*. A rise of temperature reaching its maximum within 72 hours of the injection is a *progressive reaction*. Now, since all pyrexia must resolve either by crisis or by lysis, it is clear that there may be six types of reaction. This is confirmed by observation.

1. *An immediate reaction with a fall by crisis.*—This, the mildest form of reaction, is due to the tuberculin injected, which is followed by complete immunising response. From the point of dosage it is of least significance, since the dose may be later increased and no reaction occurs.

2. *An immediate reaction with a fall by lysis.*—Here, in addition to the immediate reaction to the tuberculin, there are secondary oscillations due to incomplete immunising response. At the next injection the dose should be reduced by one-fifth the amount—that is to say, from 0·5 c.c. to 0·4 c.c.

3. *A delayed reaction with a fall by crisis.*—In this there is delayed absorption of the tuberculin followed by complete immunising response. The same dose may be repeated at the next injection.

4. *A delayed reaction with a fall by lysis.*—Here there is not only delayed absorption of the tuberculin, but an incomplete immunising response. The amount next injected should be reduced to one-half of the previous injection—e.g., from 0·79 c.c. to 0·4 c.c.

5. *A progressive reaction with a fall by crisis.*—In this there is not only an immediate reaction, but increased toxæmia from a focal reaction, eventually overcome by immunisation. This is the type of most serious significance, and if not regarded it will be followed by a violent summation temperature or by a gradual and persistent pyrexia, due to prolonged focal reaction. The dose of tuberculin must be reduced to one-tenth at the next injection—from D_61 c.c. to D_41 c.c.

6. *A progressive reaction with a fall by lysis.*—Here a focal reaction is not overcome by immunisation. The disease is lit up in the pulmonary lesion, and may progress by secondary tuberculous bronchopneumonia, of which this temperature is typical. Tuberculin treatment must be stopped, as otherwise the patient will pass into a condition of chronic tuberculous cachexia. The example of this type illustrated in the temperature chart occurred in my practice before one had appreciated the significance of the fifth type as a warning.

In their order of severity these types of temperature reaction are as follows: *a*. Immediate reaction with a fall by crisis—increase dose. *b*. Delayed reaction with a fall by crisis—repeat dose. *c*. Immediate reaction with a fall by lysis—reduce dose by ⅕. *d*. Delayed reaction with a fall by lysis—reduce dose by ½. *e*. Progressive reaction with a fall by crisis—reduce dose to 1/10. *f*. Progressive reaction with a fall by lysis—stop tuberculin.

Results of treatment.—The following are the immediate results of treating 131 patients, ambulant cases, with polyvalent tuberculin on these lines at the St. Marylebone Tuberculosis Dispensary. The record does not include patients who received prophylactic injections. The time of treatment varied from 3 to 25 months. I have used Philip's classification, and a division is made between those whose sputum contained tubercle bacilli and those in whose expectoration the tubercle bacillus was not found. The word "cure" is avoided, but the words "disease arrested" implies that the patient presents neither symptoms nor any signs of active disease.

Allsop place, W.

TUBAL GESTATION CONTINUING TO THE SIXTH MONTH AFTER RUPTURE AT THE SIXTH WEEK.

BY ROBERT NAIRN, F.R.C.S. ENG., L.R.C.P. LOND.

THE following is an account of a condition which is perhaps sufficiently rare to deserve publication in THE LANCET.

The patient, who had been married for six years, had had no children. The cervix was long and narrow, with a small os; the os had been twice dilated. Menstruation had always been painful at first, but it was regular. When seen on Jan. 25th, 1912, the patient complained that after missing one period menstruation had now gone on for nearly three weeks. Her last period had been on Nov. 24th, 1911. On Jan. 7th, 1912, menstruation began with an unusual amount of pain, especially inside the right hip. There were numerous blood clots. This lasted for about three days; it then stopped, and she felt well till Jan. 11th. She then had violent pains which lasted until the following day, when there was free bleeding for about an hour. It was not pure blood that came away, being very pale, like blood mixed with water. On the 13th there was a little "blackish" blood passed, and since then there had been a constant discharge of brownish matter.

On examination the breasts were found to be rather full, and they were slightly painful. The uterus was tender and immovable, with thickening all round it, and a brownish purulent discharge from the os. The temperature was 100·4°F. A diagnosis of miscarriage with subacute parametritis was made. On Jan. 26th the patient was curetted and given hot douches frequently. The curette went in rather to the patient's left. The discharge almost stopped after this, and the temperature remained normal until Feb. 18th, when it rose to over 100°, and the discharge increased, though it was lighter in colour. Hot douching was continued for four weeks longer, after which the temperature remained normal and the discharge stopped entirely. There was still tenderness, with a feeling of thickening about the uterus. On March 21st the patient felt quite well. On examination there were still immobility and matting about the uterus, which had enlarged to the right of the middle line, and a uterine souffle was heard. The breasts had distinctly enlarged. An amended diagnosis of either double pregnancy in a bicornuate uterus with miscarriage from the left cornu (normal or ruptured ectopic pregnancy) or fibroid of the uterus with miscarriage was now made. The uterus and breasts continued to enlarge through April and May, and the former was nearly up to the umbilicus.

Early in June I again examined the patient and found that the uterus had not continued to rise, and that the souffle was less distinct. Towards the end of June it was evident that the uterus had sunk. There was no souffle and the breasts were smaller.

When again examined on August 3rd a solid mass was felt per vaginam to the patient's right, but matting made it impossible to differentiate the parts. In view of the doubt as to the true condition a laparotomy was decided upon, and this I performed on August 8th, assisted by Dr. W. W. Moore and Dr. MacDonell. On examining the pelvis through the median incision the uterus and left ovary were found to be adherent to the left side. The right broad ligament was obliterated by a large fluctuating swelling in its substance, filling the pelvis; and the right ovary and extremity of the Fallopian tube were defined on the surface of this swelling. An incision parallel to the pelvic brim let out a great quantity of dark brown fluid, together with what appeared to be a five-months' fœtus with fair-sized placenta.

It was evident that a right tubal pregnancy had ruptured beneath the peritoneum at about the sixth week, and gestation had then progressed until about the sixth month, when it was stopped by want of sufficient blood supply. Convalescence was slow, but eventually the patient recovered perfectly.

Hastings, New Zealand.

THE DIAGNOSTIC VALUE OF ABDERHALDEN'S METHOD IN CARCINOMA.

By R. St. LEGER BROCKMAN, M.R.C.S. ENG.,
L.R.C.P. LOND.,
HOUSE SURGEON AT ST. BARTHOLOMEW'S HOSPITAL.

Abderhalden, professor of physiology at Halle in Germany, in his work on ferments of the animal system has shown that the body has the power to protect itself against substances which are foreign to it if introduced by subcutaneous or intravenous methods. The injection of cane sugar and vegetable proteids will give the serum of a dog into whose system they are so introduced the power of breaking down these substances into less complex molecules—a faculty wanting in the serum of an animal not so injected.

After Veit had shown that syncytial cells were present in various parts of the body during pregnancy Abderhalden set to work to see if he could show that any attempt was made to defend the body against such invasion, especially as the toxæmias of pregnancy were being attributed to syncytiotoxins. In 1912 he published articles describing the means by which he and his pupils had been able to demonstrate in the blood of a pregnant woman the presence of a substance which has a proteolytic action on placental albumin. He also showed that such a substance is absent from the blood of males and non-pregnant women, and further that this ferment is specific, acting on placental tissue only. To do this he made use of two methods—the dialysation method used in the following cases, which will be described later, and the optical method. In this latter case 1 c.c. of a 10 per cent. solution of placental peptone and 2 c.c. of serum from the patient under question are placed in a small polarimeter tube, the initial degree of rotation of light being at once read off. The tube is now placed in an incubator at 37°C., the tube being removed occasionally and examined by means of a polariscope. Incubation was allowed to proceed up to 36 hours. Abderhalden found that the maximum change of rotation with serum from a case of pregnancy was as high as 0·2°, whilst that when any other serum was used never exceeded 0·03°. His experiments in the case of animals gave similar results. The practical value of such methods in the diagnosis of pregnancy has been testified to by Abderhalden, Veit, Schwarz, and other observers.

The object of the present paper is to show that a specific ferment is formed against carcinomatous tissue, and to demonstrate the possibility of the existence of such being made use of in the diagnosis of carcinoma. In all the following cases the dialysation method of Abderhalden has been used.

A piece of coagulated carcinoma tissue, the preparation of which is described later, is placed in a dialysing tube, made from a fish's swim-bladder. To this are added 1·5 c.c. of serum obtained from the patient whose diagnosis is in question. Outside the dialysing tube are 20 c.c. of sterile distilled water. Into a control tube are put 1·5 c.c. of serum alone, from the patient, with 20 c.c. of distilled water outside. The surface of serum and water in both cases is covered with a thin layer of toluol to exclude as far as possible all bacterial contamination. They are now incubated at a temperature of 37° C. for 12 to 24 hours. At the end of that time 10 c.c. of the diffusiate in each case are added to 0 2 c.c. of a 1 per cent. solution of a reagent known as ninhydrin. (Ninhydrin, or triketohydrindene hydrate, with a formula  $C_6H_4\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle C(OH_2)$, gives a violet colour if heated with a solution containing minute traces of albumin, peptones, polypeptides, and amino-acids. It gives a reaction with all substances in which the amido group is in a position to carboxyl.) The solution is raised to the boiling point and maintained at that temperature for one minute. If at the end of that time no change takes place in either case the test is negative. If, however, in the case of the one containing carcinomatous tissue a violet colour results whilst the other remains colourless, then a positive result has been recorded. In many cases a brownish tint remains after boiling. This has no connexion with the unmistakable violet colouration of a positive result.

The coagulated cancer tissue was the same for all the following cases. It was obtained from a woman with a large spheroidal-celled carcinoma of the breast. As soon as the breast had been removed by a complete Halstead operation the carcinoma was carefully separated from fat and breast substance. It was then cut up into small pieces which were dropped bit by bit into a beaker of boiling distilled water to which a few drops of glacial acetic acid had previously been added. It was boiled thus for half an hour. The tissue was then washed carefully in distilled water for 12 hours. It was kept ready for use in cold storage in dis- water tilled with a layer of toluol on top. Before any was used it had been kept thus for three weeks. The water in which it had been standing was then tested with ninhydrin with a [illegible] had been negative result, thus showing [illegible] efficiently coagulated. It w[illegible] saline, and healthy human se[illegible] in all cases gave no reaction [illegible] of dialysable products, sufficient to nullify the test, in this cancer tissue was thus excluded. The dialysing tubes were then tested as regards their permeability to peptones and their impermeability to colloids. Those which fulfilled these conditions were then used for the tests—all others being rejected. In referring to certain pitfalls and sources of error which await one in doing this test I will describe the method employed in collecting the serum in these cases.

In the first place the fingers must be absolutely excluded from any direct part in the test. A drop of ninhydrin on the skin, especially if at all moist, will leave a deep violet stain. The contamination of the outer side of a tube with a finger, prior to dialysis, is sufficient to give a positive reaction on testing the diffusiate with ninhydrin. A pair of sterile forceps was used in these cases to lift tubes and tissue.

A trace of saliva will equally well give a positive reaction. This means that the mouth ought not to be used for suction whilst using a pipette. I use a rubber bulb on the end of my pipettes, though probably a plug of cotton-wool in the end of the pipette is sufficient to prevent contamination in this way. Absolute asepsis must be observed. Air-borne organisms such as B. subtilis and B. mesentericus do not, so far as my experiments go to show, nullify the test in 48 hours, but S. pyogenes aureus and, to a lesser extent, S. epidermidis albus will, even in the presence of toluol, cause sufficient change in the serum with the subsequent passage through the dialyser of the breakdown products in 24 hours, thereby rendering the result of no value. This can be understood when the liquefying action of these organisms is remembered. The presence also of hæmoglobin in the serum renders that sample utterly useless for working the test.

In these cases the blood was taken with all the precautions adopted in doing a blood culture. It was collected by means of a syringe, transferred to a sterile tube, and centrifuged at once. The serum was then drawn off and used for the test without any delay. The serum ought to be clear and straw coloured. The opalescent serum obtained from a patient shortly after a heavy meal is not reliable, since it contains dialysable substances which give a positive result in the tube containing serum alone, so that the colour obtained in that with carcinoma tissue may also be due to the same cause.

In some cases at the beginning I put my blood into cold storage to allow the separation of serum to take place. The serum so treated gave negative results, whilst serum from the same patients if used fresh gave a strongly positive result. This ferment appears to be specific for cancer tissue. Serum giving a positive reaction with carcinoma tissue gave a negative one if placental tissue or egg albumin was used. It is specific for cancer tissue in general, but will work equally well in all varieties of carcinoma, as will be seen from the following list of cases. In the first place I did the test on 25 cases which were undoubtedly carcinoma, and then on 20 odd cases in which carcinoma could be excluded beyond reasonable doubt, and in two cases beyond all doubt, as they subsequently found their way to the post-mortem room. The test was positive in all 25 cases of carcinoma and negative in the controls. In one case, which section has proved to be a carcinoma of the larynx, a negative result was recorded, possibly because only 16 hours were given for incubation.

Twenty-five Cases of Carcinoma.

Position of growth.	Number of cases.	Confirmed by section.	Nature of growth.
Tongue	6	3	Squamous celled.
Breast	5	4	Spheroidal celled.
Stomach	3	1	Columnar celled.
Bowel	2	2	Squamous celled.
Cervix	3	1	"
Rectum	2	1	Spheroidal celled.
Testis	1	1	—
Urethra	1	1	—
Gall-bladder	1	0	—
Larynx	1	0	—
Totals	25	14	

As can be seen from this list 14 were confirmed by section, the nature of the growth in these cases all being recorded. Of the other cases the tongues were inoperable with secondary glands, the remaining breast was a cancer *en cuirasse*. The stomach cases were proved by clinical signs, test meals, and laparotomy. The carcinomas of the cervix were inoperable, a laparotomy being performed in one case. The rectum, the gall-bladder with jaundice, and the larynx with secondary glands necessitating tracheotomy were clinically undoubted cases of carcinoma. In all these the test was positive.

To place against these are the controls which gave negative results. So far I have not had a patient without carcinoma who has given a positive result. The controls include healthy patients and those with fractures, septic hands, tertiary syphilitic and tuberculous ulceration. There are some other doubtful cases which have not yet been proved by operation, post mortem, or subsequent history.

In addition there are a few cases which I thought worthy of individual notice. For permission to publish these I am indebted to the various members of the clinical staff at St. Bartholomew's Hospital.

CASE 1.—A man, aged 66, was admitted under Mr. H. J. Waring complaining of stoppage of the bowels. He gave a history of increasing difficulty in getting his bowels open. The calibre of his motions had got decidedly smaller. There was no history of passage of blood or mucus. For five days he had passed neither fæces nor flatus. A colostomy was performed, an annular stricture of his pelvic colon being found. This was freely movable, and on subsequent resection proved to be a columnar-celled carcinoma. *Test positive.*

CASE 2.—A woman, aged 52, was admitted under Dr. Herbert Williamson, complaining of abdominal pain. On examination a tumour was felt rising out of the pelvis to the level of the umbilicus. Per vaginam the pelvis was occupied by a fixed mass which could not be differentiated from the abdominal swelling. There was marked œdema of one lower extremity. The patient was thin and anæmic. The diagnosis was made of ovarian cyst (? malignant). A laparotomy was performed and the swelling removed. A section showed it to be a papilliferous ovarian cyst in a degenerated condition, but with no evidence of malignancy. Subsequent to the operation the œdema of the leg has completely disappeared. *Test negative.*

CASE 3.—A man, aged 32, admitted under Mr. C. Gordon Watson with a swollen left testicle. He gave a history of enlargement of the left testicle for two years, with a rapid increase in size for two months previous to admission. A hydrocele on tapping yielded clear serous fluid. The swelling was painless and testicular sensation was lost. Wassermann was negative. The testis was removed and section showed it to be a carcinoma. This patient has been seen since and now has a local recurrence. *Test positive.*

CASE 4.—A woman, aged 34, was admitted under Mr. W. McAdam Eccles complaining of a swelling of the umbilicus. Beyond slight induration around the navel nothing could be felt. A piece removed for section showed the structure of a simple adenoma with no evidence of malignancy. A laparotomy revealed a large mass in the stomach with a secondary swelling on the deep surface of the umbilicus, which section showed to be a columnar-celled carcinoma. *Test positive.*

Conclusions.—There is here, I think, sufficient evidence to show that the blood of persons suffering from carcinoma contains a substance absent in the blood of all others, and that this substance has a proteolytic action on the carcinoma tissue only. There are also several factors which point to its being of the nature of a ferment. If the serum from a patient is left to get stale it becomes inactive, but the addition of a trace of fresh human serum will activate it again. The reaction takes place best at 37° C. At room temperature the reaction does not occur, whilst heating the serum to

55° C. for five minutes inactivates it beyond recall. If, then, as is maintained, this substance is of a protective nature it would be natural to expect to find it present in larger quantities in patients who were in good general health. The results of these tests point strongly to such being the case. I have noticed throughout the whole series that a patient with a growth of the tongue or of the breast who is in good general condition will give an intensity of colouration in 12 hours which a patient in a low state of health would fail to give in 24.

The case of carcinoma of the larynx which gave a negative result only brings this test into line with others. No pathological test known to us is infallible. It is obvious that for practical use such a test must give a reaction in the early stages of the disease. Two of the tongue cases were early localised ulcers, one intestinal growth was small and easily removable, whilst one breast case was an early scirrhus. All these gave a markedly positive reaction in 24 hours.

The facts set forth here do, I think, point to the test being of some practical advantage as an aid in the diagnosis of carcinoma, especially in such sites as the stomach and bowels, thereby allowing early surgical interference. These results have all been obtained working in the pathological laboratory of St. Bartholomew's Hospital, where the kind suggestions of Dr. Mervyn H. Gordon and Mr. Mackenzie Wallis have always been at hand.

(Since writing the above, corroborative results have been published by some German observers. Gambaroff has gone a step further and maintains the possibility of differentiating between sarcoma and carcinoma by this method.)

A NOTE ON FIVE CASES OF POROCEPHALIASIS IN MAN FROM SOUTHERN NIGERIA.

By J. W. SCOTT MACFIE, M.A. CANTAB., M.B., CH.B. EDIN.;

AND

J. E. L. JOHNSTON, M.B., B.S. LOND., D.T.M. & H. CANTAB.

(*From the Medical Research Institute, Lagos.*)

UP to the time when Sambon published his important paper on Porocephaliasis in Man[1] apparently but few cases had been recorded. In a subsequent paper[2] the same author added to his list four other records. It has, however, been pointed out by Löhlein[3] that the infrequency of the occurrence of this condition which might be deduced from the small number of cases on record does not really exist. He records how Seiffert found porocephali in 7·8 per cent. of necropsies performed on coloured railway workers in the Cameroons, and how he himself, in a series of 118 post-mortem examinations on negroes, found 10 infected with these larvæ. Borden and Rodhain have recorded cases from the Congo also, so that it would appear that porocephaliasis is not very uncommon in the natives of West Africa.

The five cases briefly described below occurred in Southern Nigeria. The first occurred at Ibadan, a large native town situated about 120 miles north of Lagos, the second at Calabar, the third at Itu, and the fourth and fifth at Degama. We are indebted to Dr. J. D. Finlay for the interesting account of the first case, to Dr. J. Currie for the notes on the second, and to Dr. A. H. Wilson for the records of the remaining three.

CASE 1.—The patient was a native man, aged about 24, who was brought to the Ibadan Hospital on July 31st, 1913. He died immediately after his admission, and in consequence the history of his case is somewhat vague. He is said, however, to have been taken ill five days previously, and the symptoms observed were fever and vomiting. At the post-mortem examination, performed by Dr. Finlay, the body was found to be well nourished, rigor mortis was present, and the conjunctivæ were noticed to be deeply stained. All the organs and tissues were intensely jaundiced. Lungs: The right lung was normal; the left lung was contracted, and the pleural cavity was filled with venous blood and dark clot. Heart: The cardiac muscle was soft. No valvular lesion was present. Liver: The liver was greatly enlarged, bile-stained, and somewhat soft. On its surface, just below the peritoneal covering, were several porocephalus larvæ, and in the substance of the organ a few more were found. There were also some lying free on the under surface of the liver. The gall-bladder was filled with thick bile. On section the liver showed the condition known as "fatty nutmeg liver." Stomach: The stomach was contracted and thickened, and Dr. Finlay compared its appearance to that of an ox. Several round worms were present in the cavity. Duodenum: The duodenum was surrounded by a hard mass which blocked the common bile-duct. On microscopical examination this mass appeared to be of the nature of an adenocarcinoma. Intestines: The small intestine appeared to be normal, but the ascending colon was adherent to the hard mass referred to above. Kidneys: The kidneys were enlarged and stained a dark green colour. The larvæ on examination proved to be those of porocephalus armillatus. Three individuals measured 18 mm., 16 mm., and 15 mm. in length, and comprised 21, 19, and 17 rings respectively. The rings in the middle of the body were 1 mm. apart, and stood out prominently. The breadth of all three was 3 mm. The cephalo-thorax appeared to be identical with that figured by Sambon for this species.

CASE 2.—The second case was that of an old Hausa woman who was found dead by the police at Calabar in September, 1913. Dr. Currie, who was called upon to make a necropsy, determined that death had been due to extensive and long-standing dysentery. In the course of his examination he found a single larva of porocephalus armillatus encysted in the edge of the liver. No more of the parasites were found in other situations.

CASE 3.—The patient, whose age was about 40, was a native of Southern Nigeria, and an inmate of Itu prison. He was a big, well-developed man, who did not appear to be seriously ill. Only a very indefinite account of his illness could be obtained. He first complained of being sick on August 5th, 1910, stating that he was constipated and had vague pains about the abdomen. At the same time he noticed that his legs began to swell. He was first seen by Dr. Wilson on August 11th, and was found to have œdema of his legs, scrotum, and abdominal walls. The abdomen was distended, and contained free fluid. There was no enlargement of the liver and spleen, the urine was normal, and the heart and lungs appeared to be healthy. He was not very weak, and could get about fairly well. The patient was removed to Ikot Ekpene. On August 15th, when he was next seen, there was an increase of the dropsy; dyspnœa was present, with a cough and frothy expectoration. On examination of the lungs moist crepitations were heard, and there was slight impairment of the resonance, especially on the right side. The patient died on August 18th. A post-mortem examination was made four hours after death. The body was well nourished. There was œdema of the legs and scrotum and slight general anasarca. On opening the abdomen a large amount of clear ascitic fluid escaped. There was no sign of peritonitis. The spleen was normal in size and appearance. The kidneys seemed to be a little congested. The liver was slightly enlarged, but in general appearance looked healthy. Scattered over its surface and in each lobe were what looked at first glance like cicatricial patches, but these proved on closer examination to be the encysted larvæ of porocephalus armillatus. Altogether there were 10 or 12 to be seen. They were all situated superficially, and were of a whitish colour. They were about half an inch long, closely coiled up, and surrounded by a thin membrane. Exactly similar larvæ were found in the lungs, but they were not so numerous as in the liver, and one of them lay an inch from the surface. The lungs were generally congested, and contained much frothy fluid. The bronchial tubes showed signs of congestion. There was no increase of fluid in the pleural cavities, a few slight adhesions were present, but there were no signs of recent pleurisy. The heart was normal. The pericardium contained an excess of fluid. The intestines were normal in appearance, and no larvæ were seen on their surfaces. The mesentery and the glands were not especially examined.

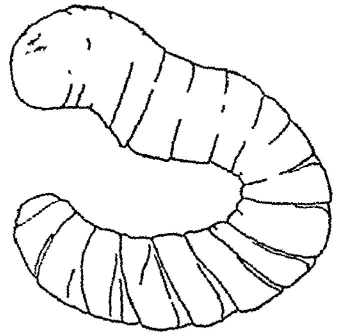
CASE 4.—The patient, a male native, aged about 50, was a prisoner from the Ahoada district of Southern Nigeria. In April, 1913, he was admitted to hospital at Degama for observation, but his symptoms appear to have been somewhat vague and indefinite, and in the same month he was transferred to Bonny. In August he was re-transferred to Degama. On re-admission it was noted that he was in "an emaciated and generally feeble condition," but no definite disease was diagnosed to account for his condition. His asthenia was progressive, and he could only walk feebly for a few yards at a time. He was discharged on Sept. 5th, but remained in the prison awaiting transport to his own country. About the same date it was observed that his abdomen was somewhat swollen, and on examination the presence of free fluid was detected. Two days later the feet and legs became œdematous, and asthenia became extreme. On the 11th dyspnœa and cough supervened, and the lungs were found to be congested. There was no fever and the urine was normal. Two days later the patient died. At the post-mortem examination, which was made by Dr. Wilson on the same day, the body was found to be emaciated and the legs slightly œdematous. Thorax: The heart appeared to be normal. There were a few old adhesions on both sides in the pleural cavities. Both lungs were much congested, and on the surfaces ecchymoses were found. On section a large amount of blood and frothy fluid escaped, the condition being one of general congestion and œdema. The lungs were searched for larvæ, but none was found. Abdomen: On opening the abdomen a large amount of limpid fluid escaped. There was no peritonitis. The liver was normal in colour and appeared to be below the usual size, and was tough in consistency. On its surface was a number of cicatricial patches. On further examination a nodule about ½ inch in diameter was found on the surface of the right lobe. This proved to be an encysted larva enclosed in a very tough and fibrous capsule. On thoroughly searching the liver four similar encysted larvæ were found. The mesentery was searched for larvæ, but with negative result. The spleen, kidneys, pancreas, and stomach and intestines were all normal.

CASE 5.—The patient, a Kroo boy, aged about 17 years, was admitted to Degama Hospital on July 7th with ulceration of the cornea of the right eye. He made no further complaint, and the examination of his physical condition was negative. He was, however, reported to have been losing strength recently and to have been performing his work in a languid fashion. Whilst in hospital his condition was one of gradual and progressive asthenia, and he died on July 14th. Two weeks before his death his gait became staggering, his knee reflex was lost, and he complained of some vague pains about the legs; but with the exception of rapid action of his heart no local signs or symptoms could be detected, and no evidence of cardiac incompetency was found. At the post-mortem examination the body was found to be fairly well nourished and presented no abnormal appearances. Thorax: The pericardium was adherent to the heart, the right ventricle thin and dilated, the left ventricle normal, and the valves normal. The lungs were very small but appeared to be healthy; no porocephalus larvæ were found although careful search was made for them. Old pleuritic adhesions were present on both sides. Abdomen: The abdominal cavity contained a little free peritoneal fluid, but there were no signs of peritonitis. The liver was slightly enlarged, there was general hepatitis, and the organ presented a nutmeg appearance. On the surface two patches with a superficial resemblance to cicatrices were found, which when cut into were seen to be encysted larvæ of porocephalus. On making successive sections through the liver about ten of these larvæ were found. None was more than a half to three-quarters of an inch beneath the surface. One larva was found in the mesentery. The kidneys, pancreas, stomach, and intestines were all normal.

The parasites from the last case had unfortunately been considerably damaged in dissection, and only one complete individual could be pieced together. This specimen (see figure) consisted of 20 rings, and measured 17 mm. in length and 3 mm. in breadth. An unopened cyst from the same case measured 9 mm. by 6 mm. by 3 mm. The larvæ differed somewhat from those of the other cases. They were smaller, and the rings, which were broad and bandlike, were set more closely together. The heads also appeared to be more bulbous. Such differences in appearance may have been due to the larvæ having been in an immature condition.



Porocephalus from Case 5, magnified. Actual length, 17 mm.

Very various opinions are held with regard to the effects of porocephalus larvæ on their human host. Löhlein seems to believe that they are harmless, but Chalmers states: "The presence of the parasite in the human body sets up inflammation of the lungs and peritoneum, but it does not appear to irritate the alimentary canal or liver."

In the first two cases recorded above sufficient evidence of disease was detected at the necropsies to account for death without attributing any action to the presence of the larvæ. In the second case only a single porocephalus larva was found in the body, but there was evidence of severe and chronic dysentery, and in the first death would appear to have been due to the presence of a tumour surrounding the duodenum and blocking the common bile duct, and the few symptoms noted, and the pathological appearances observed, were probably due to this cause. The possibility that irritation caused by wandering larvæ might have played some part in the production of the tumour should not, however, be forgotten, although no evidence of any such predisposing cause was detected at the necropsy. The three cases recorded by Dr. Wilson (Nos. 3, 4, and 5), on the other hand, suggest that the presence of porocephalus larvæ may have serious pathological significance. No definite cause of death was discovered at the post-mortem examinations, and Dr. Wilson himself considered that the fatal termination in each case had at any rate been accelerated by the presence of the larvæ. These three cases presented a peculiar clinical picture, and the pathological conditions found after death were somewhat similar. The chief symptoms were progressive weakness, œdema, and dyspnœa, without any very definite signs to account for the physical conditions. The patient in Case 5 developed some interesting nervous symptoms shortly before death. A larva was found in the mesentery, a fact which suggests the possibility that wandering larvæ may have been responsible for some of the symptoms. It is interesting to note that Waldow found small cysts containing calcified porocephali in the liver, omentum, mesentery, and pleura of a native who died in the Cameroons with symptoms of meningitis.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE RESULT OF CEREBRAL DECOMPRESSION IN A CASE OF EPILEPSY.

By Allan Watson, M.B., Ch.B., D.P.H.,
D.T.M. & Hy. Edin.

The results of surgical treatment in cases of idiopathic epilepsy have been, on the whole, so discouraging that the following notes on a case which was markedly benefited by Kocher's decompression operation may be of interest.

The patient, a boy aged 16 years, was sent to the East Suffolk Hospital from the Ipswich Mental Hospital on Sept. 26th, 1912. He suffered from frequent epileptic fits, and was certified as being a person of unsound mind. He was an illegitimate child, and was born prematurely at about the end of the eighth month. At the time of his birth his father was 20 and his mother 19 years of age. When the patient was about 3 months old he suffered from severe "convulsions," but he was otherwise healthy until he was in his eleventh year. He is said to have had a fall on his head when about 5 years of age, but he was not unconscious after the accident, and was apparently none the worse for it. He commenced having epileptic fits when he was 10½ years old, and shortly afterwards some paresis of the right hand and arm was observed. The fits at first recurred about once every two days. When he was about 11 years old he injured his left eye and had to have it enucleated. Towards the end of November, 1911, the fits became much more severe and increased greatly in frequency, recurring 10 or 12 times a day. About this time also he began to show signs of insanity. He was admitted to the Ipswich Mental Hospital on Dec. 4th, 1911, showing the following signs of insanity, as stated on his certificate: "He talked of committing suicide and had asked for a rope and a razor to do so. He had fits of unprovoked laughter, and at times talked incoherently. He had no recollection of dates. He had occasional fits of violence and excitement." While he was an inmate of the Mental Hospital he had an average of about 10 fits daily.

Neither of the patient's parents suffered from epilepsy, insanity, alcoholism, syphilis, or tuberculosis. A maternal uncle suffered from general paralysis of the insane, and a paternal uncle suffered from melancholia. His father also had had a great-uncle who was insane for many years.

The patient was a fairly well-developed, intelligent-looking lad. His features were small and his forehead was narrow. His complexion was fair. There were no marks of injuries about the head, but the skull was distinctly flattened over the left parietal region. The following cranial measurements were noted: (1) Circumference taken just above level of superciliary ridges, 21¾ inches; (2) distance from nasion to inion across top of skull, 15 inches; (3) distance from right to left suprameatal points across top of skull, 12 inches. The colour of the right eye was blue. The pupil was of medium size and reacted sluggishly to light and accommodation. The knee-jerks were present and were fairly active. He seldom used his right hand and arm, which were less well developed than the left. The right elbow- and wrist-joints were usually held flexed, but he could extend both voluntarily. He answered questions promptly as a rule, but in a rather listless manner. His memory was fairly good for recent events, but not good for remote events. At times he was rather incoherent. He took very little interest in his surroundings. There was no evidence of congenital syphilis or of tuberculosis.

The patient was kept under observation for a week after his admission to hospital. He had daily from 12 to 15 fits of varying severity. There was never an aura of any description. Occasionally the fits commenced with a cry which was sometimes a yell, but more often a loud groan. The tonic spasm nearly always seemed to commence in both arms simultaneously; it usually, but not invariably, became general. The eye generally turned inwards and upwards, but sometimes outwards and upwards. The clonic spasm usually began on the right side of the body, but the muscles first affected varied; occasionally it began on the left side, and on a few occasions both sides seemed to be affected simultaneously. The clonic spasm usually became general. He was invariably unconscious during the fits for several seconds at least. Occasionally he was unconscious for a few minutes after a fit, but more generally he was conscious, though dazed and unable to speak for a little. He frequently passed urine or fæces involuntarily during or immediately after the fits.

An operation was performed on Oct. 4th, 1912. The patient was trephined over the left Rolandic area, and the opening was enlarged with gouge forceps until it measured about 3 by 2 inches. The dura mater was reflected, but no abnormality was noted save slight flattening of the cerebral convolutions. The brain surface was covered with Cargile membrane and the wound was closed in the usual manner. The patient remained unconscious for about 15 hours after the operation. When he recovered consciousness it was noticed that his right arm and leg were paralysed. On Oct. 7th he had one rather severe fit. The tonic spasm began in the right arm; the clonic spasm was general. Some hours later it was noted that he could move his right arm and leg voluntarily. By the 12th he had regained complete control over both limbs. He could use his right arm very much better than he could before the operation, and it was no longer held with the wrist- and elbow-joints flexed. His mental condition improved very rapidly and remarkably; he became bright and cheerful, and took an intelligent interest in everything. He had one very slight fit on the 23rd and another on the 24th. On

Nov. 5th he was discharged. He was apparently quite sane and the paresis of the right arm had completely disappeared.

A report on the patient received six months after the operation stated that he had had 12 slight fits since his discharge from hospital, but was quite sane and in excellent health.

I am indebted to Dr. Herbert H. Brown, honorary surgeon to the East Suffolk Hospital, for permission to publish the notes on the case.

Evanton, N.B.

TORSION OF THE PEDICLE OF AN OVARIAN CYST ON EACH SIDE,

WITH ADHESION OF AN INFLAMED APPENDIX VERMIFORMIS TO THE CYST ON THE LEFT SIDE.

BY CECIL MEREDYTH-JONES, M.B., B.S. LOND.,
HOUSE SURGEON AT WESTMINSTER HOSPITAL.

A WOMAN, aged 50, was admitted to Westminster Hospital on Dec. 30th, 1912, under the care of Mr. W. G. Spencer, complaining of violent pain in the abdomen most marked in the *right* iliac fossa and hypogastrium. She had noted the abdomen gradually enlarging for more than a year, and at times had felt "vague movements," but had not consulted a medical man. Her menstrual periods had become irregular for two years, but she had had some blood-stained discharges at intervals of from three to six months. She had first felt pain after a slight strain some two months before; pain had recurred at intervals, but was relieved by lying down. The acute attack of pain commenced on Dec. 27th, since when she had had no motion, and felt nausea but had not vomited.

On admission the patient was in distress with pain and great thirst. She had a dry, furred tongue, the pulse-rate was 130, and the temperature was 99·6° F. The abdomen was not markedly distended; there were no coils of intestines to be seen. A lobulated mass could be felt in the hypogastrium extending towards the *right* iliac region, which was tense and could be swayed a little, but it did not fluctuate; except over this the abdomen was resonant to percussion. Per rectum the pelvis could be felt to be occupied by a semi-fluctuating mass which pitted on pressure; the uterus was pushed forwards and downwards.

Mr. Spencer diagnosed an ovarian cyst with a twisted pedicle; the collection in the pelvis was supposed to be peritoneal fluid shut off from above by adhesions. A Pfannenstiel's incision—i.e., a curved incision through the skin and anterior sheath of the recti with a separation and retraction of the muscles—was made midway between the umbilicus and pubes. The bladder presented in the wound, for although it had been emptied it had been drawn up by the ovarian cyst, to which it had previously become adherent; also some intestinal adhesions were separated. Then a cyst of the size of a large cocoa-nut was found which had arisen from the *left* ovary, but its pedicle having undergone axial rotation the cyst had come to occupy the *right* of th [illegible] and *right* iliac fossa, while the [illegible] rotated, so that its *left* cornu looked backwards and its *right* forwards. To this cyst the appendix was densely adherent, the appendix itself being excessively long, thickened, and kinked. It was removed and the stump buried in the cæcum. Then the cyst was brought out; it was blue from venous congestion but not yet gangrenous; its long pedicle had been twisted through about a circle, and its blood-vessels were thrombosed. On further examination after removal the cyst proved to be a multilocular ovarian cyst, some of the cysts containing putty-like remains of blood-clot. After drawing up the uterus and separating more adhesions the mass in the pelvis was found to be the remains of a right-sided multilocular ovarian cyst, the pedicle of which had become twisted, the cyst wall gangrenous and ruptured, but the contents had been confined to the pelvis by the adhesions above. After removing it the pelvis and rest of the lower part of the abdomen were sponged dry, a glass tube was passed into the pelvis, and the abdominal wall sutured in layers around it. The patient made an uninterrupted recovery and was able to leave for a convalescent home within a month.

The patient appears to have developed a multilocular cyst from each ovary about the size of a large cocoa-nut. During this time an exceedingly long appendix became kinked and inflamed, which led to adhesions to the cyst on the *left* side, to slow twisting of the pedicle, with the formation of adhesions to the bladder and intestines. The slow development of this condition, with the twisting of the fundus of the uterus, led to the cyst on the *right* side being crammed down into the pelvis, in the course of which its pedicle became twisted, the sac wall gangrenous, and rupture followed. It would appear that the acute symptoms were produced by the rupture of the *right* ovarian cyst in the pelvis. The complicated nature of the case had to be unravelled in the course of the operation.

I am indebted to Mr. Spencer for permission to publish the notes of the above case.

Westminster Hospital.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Pyelo-Radiography.

A MEETING of this section was held on Nov. 11th, Mr. G. H. MAKINS, the President, being in the chair.

A discussion took place on Mr. F. S. KIDD'S paper published in THE LANCET of Oct. 25th.

Mr. S. G. SCOTT spoke of the details of the radiographic examination in such cases. He said that the couch should be raised on wooden supports, as the usual couch used in radiography was not high enough. The surface should be of polished wood with a loose covering of thick felt, so that the patient could be slipped freely along it without muscular effort on his part. At the time of the examination he should be slipped to the foot of the couch, his legs raised and thighs supported. A suitable catheter was one which was divided into sections, opaque areas of one inch alternating with transparent areas of a quarter of an inch. After the collargol had been injected the patient should be put back into his original position, and the plate so arranged that the last rib occupied its centre. Each kidney should be skiagraphed separately. Compression from above aided the examination. The pelvis of the kidney should be kept full during the exposure, and the tube through which the collargol ran should not be clamped, because this led to leakage round the catheter. The exposure occupied from 15–20 seconds, and then the collargol should immediately be run out. He did not think it advisable to watch the pelvis filling by the fluorescent screen. The whole process should last a few minutes only.

Mr. J. W. THOMSON WALKER said that the procedure required the coöperation of the surgeon with the radiographer. The patient should remain in bed for a day or two afterwards. It could not be denied that there was a certain element of danger, so that it should not be employed except in those cases where the information which it gave was important enough to justify its use. One class of case to which it was applicable was where hydronephrosis was diagnosed, and by pyelography none was seen. In this way an operation was avoided. In another class were cases where renal symptoms were present, but the kidney was not palpable. A third consisted of cases of renal tumour, and a fourth those in which radiography showed a shadow of doubtful origin, and in which by pyelography the relation of the calyces of the kidney to the shadow was made clear. One case had been described where the renal pelvis had been ruptured. It was not justifiable to use force in introducing the fluid, and the inflow should be stopped if pain was induced. This, however, was not always a reliable guide. No anæsthetic should be employed. If the fluid did not run in with a continuous flow another warning of danger was afforded. He had lately used solutions of from 10 to 15 per cent., or even 20 per cent., to ensure a good shadow. In one case he had found œdema of the fat around the kidney, which he ascribed to this method of examination.

Mr. A. RALPH THOMPSON said that he had found great assistance from pyelography in the planning of operations upon kidneys, especially when they were out of place, and al [illegible]
relation of the kidney to [illegible]
He thought that a knowl[illegible]
was important, and should if possible be standardised.

Mr. A. E. JOHNSON had found the method of use in cases of unilateral renal pain of unknown origin, in doubtful cases of hydronephrosis and pyonephrosis, in congenital defects of the urinary system, in abdominal tumours, and in the interpretation of X ray shadows. It was of great value in demonstrating early dilatation of the pelvis. He recommended that the tip of the catheter should be identified by the screen before running in collargol, and advised against compression from above. In his opinion the dorsal position was the best. In movable kidneys he had sometimes obtained advantage by examination of the patient in the standing posture.

Mr. KIDD replied.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases and Specimens.

A MEETING of this section was held on Oct. 24th, Dr. LEONARD G. GUTHRIE, the President, being in the chair.

Dr. C. E. ZUNDEL showed two cases of *Infantilism.*

CASE 1.—The patient was a girl, aged 13 years, the eldest of three children, the others being healthy. She was very small at birth, and "does not seem to have grown since she was five years old." The patient was 3 ft. 6 in. in height, and her weight was 2 st. 10½ lb. The face was intelligent; the skin was dry; the hair was fair and rather coarse. There was no suggestion of appearance of puberty. Urine: Acid, pale, specific gravity 1004, contained 1/20 albumin, and a few granular and fatty casts were found in the centrifuged specimen. No polydipsia; occasional nocturnal enuresis.

CASE 2.—The patient was a boy aged 13 years. Since the age of 2½ years he had had polydipsia. No other illness before or since, but his excessive thirst had been constant. His father and one brother had also suffered from diabetes insipidus. Condition: Thin, childish, weight 2 st. 1½ lb., height 3 ft. 6 in.; thymus, thyroid, and pituitary gland apparently normal. Drank on the average 14 pints per diem. Disliked sweet things; appetite poor. Urine: Specific gravity 1001, no albumin, no casts, urea 0·5 per cent. Wassermann reaction negative.

Dr. E. A. COCKAYNE showed a case of Constriction of the Arm by Amniotic Bands.

The patient, a girl aged 3½ years, showed a narrow fibrous band completely encircling the right upper arm, causing slight constriction, and another which deeply constricted the forearm just above the wrist; in flexion—the intra-uterine position—the two scars were at the same level. The scar tissue was adherent to the deeper structures and the bone felt grooved, but a skiagram showed that it was not involved. The right arm and hand were well developed and larger than the left, showing that there had been no pressure on the arteries.

Dr. COCKAYNE also showed a girl, aged 1 year and 4 months, with Hemiplegia and a very extensive Nævus.

The birth was easy, but the child was said to have been "born in convulsions." The mother attributed the condition to her having seen a cripple with a very large birthmark when she was three months pregnant. The mother noticed the nævus at birth, but was not sure whether the hemiplegia was present then or came on later. It was first noticed after the child had had a severe left-sided fit at the age of six weeks. She had had similar fits at intervals up to the age of one year. There was complete left hemiplegia with spasticity of the arm and leg, and the left side, including the face, was noticeably smaller than the right. There was very extensive port-wine staining of the skin of the scalp, face, arms, legs, and part of the trunk. It was fairly symmetrical and followed a posterior root distribution. Wassermann's reaction negative.

Dr. J. PORTER PARKINSON showed a boy, aged 5 years, with Rheumatoid Arthritis.

In July, on admission to hospital, the patient was pale and thin, with wasted muscles. The knees, ankles, wrists, and elbows were swollen and spindle-shaped, with soft, pulpy swelling. Enlarged glands could be felt in the axillæ and groins, but the spleen could not be felt and showed no evidence of enlargement. Teeth good; no evidence of gastro-intestinal derangement. Weight 2 st. 1 lb. Wassermann and von Pirquet's reactions normal. Temperature occasionally up to 100° F. Treatment consisted of massage, &c., a course of arsenic internally, and, later, rectal injections of polyvalent antistreptococcus serum, but without effect. The patient left the hospital at the end of July, and on readmission in October, in addition to the conditions described above, there were spindle-shaped enlargements of all the joints of the fingers and slightly of the metacarpo-phalangeal joints of both hands, and the left hip-joint had become fixed in partial flexion.

Dr. T. R. WHIPHAM showed three cases of Under-development.

CASE 1.—A rickety boy, aged 2 years and 3 months, who was very undersized, being only 2 ft. high and weighing only 11 lb. The anterior fontanelle was open and the patient had only seven teeth. [illegible]

CASE 2.—A boy, aged [illegible]
well proportioned and in [illegible]
9 in.; weight 1 st. 8½ lb. [illegible] the skin and subcutaneous
suffered from tuberculosis of the skin and subcutaneous tissues. He had been treated with thyroid extract and more recently with polyglandin, with some improvement.

CASE 3.—A girl, aged 18 years, showing signs of hyperthyroidism. She had the development of a girl aged 10, her height being 4 ft. 1½ in. and her weight 4 st. 10½ lb. There was an absence of mammary development, also of both pubic and axillary hair, and menstruation had not occurred. The girl had attended school, but was not quite up to the normal standard and her memory was not good.

Dr. WHIPHAM also showed a girl aged 6 years with Enlargement of the Liver and Spleen associated with Jaundice.

The patient was born jaundiced, the colour being "green-yellow," and the condition lasted for six weeks. Since then no jaundice had been noticed until February of this year. The onset was sudden, and when the patient was first seen in May she was deeply jaundiced, being of an olive-green colour all over. The liver was greatly enlarged, extending to the umbilicus, and the spleen was also of considerable size, extending down to the same level. The blood count at this time showed red corpuscles, 4,824,000 per c.mm.; white cells, 15,200 per c.mm.; polymorphonuclears, 39 per cent.; lymphocytes, small, 53 per cent.; lymphocytes, large, 6 per cent.; and eosinophiles, 2 per cent. No myelocytes or mast cells were seen. The motions were brown or yellow in colour, not acholic, but the urine was deeply coloured and contained bile-pigment. Wassermann reaction negative. After persisting for three months the jaundice had been gradually getting less during the last two months. The liver edge was now 1½ in. above the umbilicus, but the spleen had slightly increased in size. A recent count showed a change in the blood picture: Red corpuscles, 2,360,000 per c.mm; white cells, 38,000 per c.mm.; polymorphonuclears, 50 per cent.; lymphocytes, small, 28 per cent.; lymphocytes, large, 4·7 per cent.; myelocytes, 13·3 per cent.; eosinophiles, 3·7 per cent; and mast cells, 2·2 per cent. Nucleated red corpuscles were present and a few of the myelocytes contained eosinophile granules. Hydropic degeneration of the nucleus was frequent, especially in the myelocytes and the large lymphocytes. The urine was still pigmented and contained bilirubin, but no urobilin.

Dr. LEONARD GUTHRIE showed a case of Congenital Insufficiency of Ocular and Facial Movements in a boy aged 4 years.

At birth imperfect closure of the eyes was noticed and also that the face was devoid of expression. The whole face was motionless as far as the mouth; the skin of the face was smooth and not tightly stretched. The eyes could not be completely closed, the eyeballs were in mid-position, and the only ocular movement was convergence downwards and inwards. The pupils were equal and reacted to light, less so to accommodation. Laughter was only represented by guttural grunts. The orbicularis oris was not paralysed, this being probably due to association of its action with that of the tongue. Electrical reactions could not be obtained in any of the facial muscles except the orbicularis oris. The condition was regarded as an unusual form of myopathy affecting muscles supplied by the third and the seventh nerves.

Dr. F. LANGMEAD showed a case of Cretinism.

The appearance of the patient, a female child aged 5 months, was characteristic. The child was shown because she exhibited two features which are characteristic of Mongolian imbecility rather than of cretinism—(1) markedly incurved little fingers and (2) congenital morbus cordis.

Dr. E. BELLINGHAM SMITH showed a case of (?) Cerebellar Encephalitis.

The patient, a boy aged 8 years, was admitted as a case of cerebro-spinal meningitis. On July 25th there had been a sudden onset, with headache, vomiting, and aching pains On admission on the 26th the boy was drowsy, with flushed face, rigidity of the neck muscles, and some retraction of the head. The abdomen was retracted, the reflexes were exaggerated, the plantar reflexes extensor, and Kernig's sign and ankle clonus were well marked. Temperature, 103° F. Lumbar puncture revealed a turbid fluid. not under pressure containing 0 075 per cent. albumin; globulin a small precipitate. glucose present, also many polynuclear cells and large lymphocytes No organisms seen; cultures sterile On August 8th commencing optic neuritis was noticed which became more marked. On Sept. 4th fluid from a second lumbar puncture was also sterile. 9th: No paresis of the limbs but well-marked ataxia, the incoördination being equally present on both sides. 15th: The patient was put on iodide of potassium, since when symptoms have rapidly cleared up and the child seems now practically well.

Dr. BELLINGHAM SMITH also showed a case of Infantile Paralysis of early onset and with unusual deformities.

The disease came on when the child was only two months old. The patient was quite unable to sit up and usually lay with both knees flexed and the hips abducted so that the thighs were at right angles to the pelvis. The left leg could be readily brought down into a direct line with the trunk, but the right was incapable of complete inward rotation and adduction.

Dr. PORTER PARKINSON showed a specimen of Neoplasmoid of the Sigmoid Flexure from a boy aged 5 years.

When admitted to hospital on July 17th there was a distinct, rounded, movable, tender lump of the size of an orange in the right iliac fossa. On Sept 29th, after several motions containing large quantities of blood, the child died. At the necropsy the lump was found to be a distended sigmoid colon lying in the right iliac fossa and adherent to the adjacent small intestine. The walls of the sigmoid were much thickened with hard, whitish growth, the inner surface being ulcerated. A microscopical section showed somewhat large, rounded, and tailed cells packed in the meshes of fibrous tissue alveoli.

In the opinion of Dr. Porter Parkinson and of others the growth was a carcinoma.

Dr. J. D. ROLLESTON showed a specimen of Extensive Diphtheria of Trachea and Bronchi from a girl aged 5 years.

The specimen showed membrane closely adherent to the posterior surface of the epiglottis and interior of the larynx, from the lower end of which a thick continuous tubular cast extended to the bifurcation of the trachea and passed into each of the bronchi.

Dr. F. G. CROOKSHANK showed a skiagram of a case of Anomalous Development.

The lower limbs were small, immobile, and presented webbing between the thigh and the calf. At the post-mortem examination it was found that the spinal column terminated at the twelfth dorsal vertebra in a bony mass of small size The spinal canal was completely closed. There were 12 pairs of dorsal nerves, but no lumbar nerves at all, and the legs were seemingly not innervated. A very rudimentary sacrum and coccyx were present. For several months before and after the date of the child's conception the mother had been in close daily association with a little boy, paralysed as the result of Pott's disease, who died when the mother was four months pregnant.

Mr. DUNCAN C. LL. FITZWILLIAMS showed a specimen of Extrapleural Lipoma from a child aged 6 years.

The case had been shown at the meeting of the Section in January as a case of lymphangioma, resembling hernia of the lung. The swelling gradually became larger, and in September the lump was exposed and removed. It proved to be a pure lipoma with very little fibrous tissue. The portion in the neck communicated by a narrow isthmus growing down behind the subclavian artery with a much larger portion which lay within the thorax outside the parietal pleura. The tumour, which was very soft, was removed whole.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases.—The late Mr. E. Nettleship.—Disease in the Eyes of Animals.—Obstruction of the Lacrymal Duct and its Treatment.

A MEETING of this section was held on Nov. 5th, Sir ANDERSON CRITCHETT, the President, being in the chair.

Mr. SYDNEY STEPHENSON showed a case of Brawny Scleritis at an early stage, which Mr. E. TREACHER COLLINS thought was a tenonitis. He had had a case of this condition which persisted for a long time, as had this one.—Mr. W. T. HOLMES SPICER reminded the meeting of a case with a similar appearance which he showed at a former meeting under the title "solid œdema of the conjunctiva." That, however, had a syphilitic origin, which apparently was not the case here.—Dr. D. LEIGHTON DAVIES spoke of a case under his care with a similar appearance. A small portion examined showed round cells without a stroma. He enucleated, and on bisecting the globe found a darkly pigmented sarcoma. He suggested that the present case was sarcoma.

Mr. J. L. BARLEY showed a case of Keratitis Punctata.

Mr. C. KILLICK exhibited a case of Persistent Hyaloid Artery.

Dr. A. S. COBBLEDICK showed an example of Ectasia of the Cornea four years after a perforating wound; also a case of Rupture of the Choroid in a Myope following Labour. The latter case he regarded as unique.

Mr. N. BISHOP HARMAN showed a patient with New Growth causing detachment.

Mr. GEORGE COATS exhibited a Dog with Keratitis.

Mr. E. CHATTERTON showed a case of Tuberculous Iritis in order to elicit opinions as to the value of tuberculin injections for the condition.—Mr. S. H. BROWNING said he had treated a number of such cases with tuberculin, and he knew of no case in which hæmorrhage had followed its use. The French believed the hæmorrhages which occurred were of tuberculous origin.—Mr. M. S. MAYOU stated that he had treated numerous cases of tuberculous iritis with tuberculin, and had not seen hæmorrhages during the treatment; there was absorption of the nodules, and subsidence of the iritis. It was the most successful treatment. He commenced with 1/10,000th, and worked up to 1/250th mgm. T.R. Where there was lung trouble also, a very small dose caused severe reaction, and it should be given very cautiously.—Mr. A. MACNAB said he had recently treated two cases in this way, and both did very well.—Mr. ARNOLD LAWSON gave confirmatory experience.

Mr. J. HERBERT PARSONS showed a Central Unilateral Retinitis.

Dr. A. HUGH THOMPSON exhibited a case of Choroiditis starting as a ring round the macula.

The PRESIDENT made sympathetic reference to the death of Mr. Edward Nettleship, which was a loss not only to the society but to the world of ophthalmology. Though evidently in failing health, his mental vigour was such that he took part in the discussions at the recent Congress of Medicine. The speaker's father and Mr. Bowman had the highest opinion of Mr. Nettleship's pathological knowledge in the early days, and that opinion had been amply justified since. A resolution of condolence with his relatives was carried by members upstanding.

Mr. G. COATS read a paper in which he reported some examples of Disease in the Animal Eye. He described a form of keratitis characterised by the presence of a superficial vascular opacity of the cornea. The disease was of long duration and had no evident association with distemper or other general illness. It sometimes occurred in more than one member of the same litter. Pathologically, it consisted in a replacement of the superficial layers of the cornea by a layer of inflammatory tissue. The human condition which it most nearly resembled was trachomatous pannus, but it differed from that disease in the absence of follicles, and of scarring or distortion of the lid, as well as by its not being confined to the upper part of the cornea. A case of retinal degeneration following distemper was described. The retinal changes were peculiar in that it was the bipolar cells of the inner nuclear layer which were chiefly affected, the ganglion cells showing only slight, and probably secondary, changes, the outer layers being mostly intact. In places, however, the rods and cones and their nuclei were also atrophied. These changes were probably to be explained by the presence of a circulating toxin with a specific affinity for the retinal bipolar cells, analogous to the specific action of nicotine on the ganglion cells. A description of some cases of choroido-retinal degeneration and inflammation was prefaced by a discussion of the pathological points of distinction between these two conditions. A profound atrophy of the retina without adhesion to the choroid must be a degeneration. In old standing cases of degeneration, however, an adhesion between the two membranes occurred, but it was usually not very intimate; the line of demarcation remained well defined, and the elastic lamina of the choroid was intact. The occurrence of cicatricial tissue was certain proof of precedent inflammation, and where it was present the adhesion was dense and the layers of the choroid and retina were distorted and disorganised, instead of being merely atrophic. A degeneration was often fairly uniform over a considerable area; an inflammation was patchy. Examples of choroidal-retinal degeneration in a dog, racoon, wolf, wild sheep, ferret, wallaby, and hyæna were shown. The racoon appeared to be an albino, yet a little pigment was present in the epithelium of the ciliary body and anterior part of the choroid, showing that pure albinism could not be diagnosed without a microscopical examination. The racoon also showed nystagmus—a condition occasionally described in the lower animals. A case of choroiditis, cyclitis, and keratitis in a bear, and one of anterior choroiditis in a peccary were also illustrated. Two instances of canine irido-cyclitis were reported. The first was of plastic type, and was peculiar only in its occurrence in the dog, in which animal the condition appeared to be rare; the second, also in a dog, was characterised by an enormous thickening of the iris, due to infiltration with mononuclear cells of a special type. Posterior synechiæ and other features of plastic iritis were absent. The cause of the irido-cyclitis was obscure in both instances.—The paper was discussed by Mr. TREACHER COLLINS, Mr. J. B. LAWFORD, Mr. SEWELL (veterinary surgeon), Dr. RAYNER D. BATTEN, Mr. BISHOP HARMAN, Mr. HOLMES SPICER, Mr. W. LANG, Mr. R. R. CRUISE, and the PRESIDENT, and Mr. COATS replied.

Mr. CHARLES WRAY read a paper on Obstruction of the Lacrymal Duct and its Treatment. He believed it was a mistake to remove the sac when syringing failed without attempting to cure by means of styles, or styles and probing combined, and thought it was not unlikely that ectropion and its sequelæ might follow excision. Too much was heard of the satisfactory and immediate results, but too little of bad ones and of recurrences. After referring to the danger of adrenalin and chloroform when used at the same time, stress was laid on Harrison Butler's operation. According to the speaker, all cases of epiphora should be rhinoscoped, though he admitted he had received little or no help from the rhinologist. Mr. Wray treated his cases in the following way. He injected cocaine by Mellen's method, and instilled a drop into the conjunctival sac. A Bowman's probe was then passed into the sac and the point pushed forward under the palpebral ligament. He then cut down on the guide, taking care to note the click of the knife on the probe. So far the procedure was quite painless. He then placed crystals of novocaine in the sac and had recourse to probing. At times, if the stricture was impermeable he forced a passage through the posterior wall of the duct. A piece of strapping was then placed just below the sac, so that the style did not press on the skin. A special style—gold-plated, and obtainable from Courlander, of Croydon—was then passed, and the latter was so constructed that when a piece of strapping was placed on its arms it could not move. Whilst it was *in situ* argyrol 5 per cent. was used three times a day, or such other application as might be desirable. Later, when a firm-edged fistula had formed, the patient was instructed to irrigate the sac three times a day, passing the style at night, and taking it out in the morning. To cure the fistula it could be dilated, and whilst stretched all the cicatricial tissue cut away, after which the edges of the wound were brought together and covered with collodion. He proceeded to criticise the operations of Toti, Eichen, and West. The first of these consisted in making a large open window between the sac and the nose, and as the nose in cases of lacrymal obstruction was so very often diseased the operation, in his judgment, could scarcely receive the approval of ophthalmic surgeons. And the patient experienced considerable annoyance on blowing his nose, and the operation provided no vertical tube like the duct to carry a flow of tears opposed to the entry of organisms to the sac. Eichen side-tracked the tears to the antrum—i.e., converted this cavity into a pool of stagnant tears. It also had the same objections as those urged against Toti's operation. West's operation was for obstruction low down in the duct, and consisted in removing its nasal wall. It was better than the two foregoing operations, as some of the duct was left, but it had the serious objection that auto-lavage and autoprobing were impossible. The aim of the operation was to make a permanent fistula in the middle meatus, but the task of making one in erectile or semi-erectile tissue in a canal the size of a crow-quill was almost impossible; but in the event of the duct being kept open by constant probing *viâ* the nose, or canaliculus, the erectile tissue would be so damaged that a fibroid stricture would be bound to follow. Mr. Wray said that his object was not so much to attract attention to his own operation as to obtain a formal expression of opinion as to the value of the newer operations of Toti, West, and Eichen.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Vital Principles of Foodstuffs.—Paratyphoid Fever.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Nov. 7th, Dr. T. WARDROP GRIFFITH, the President, presiding.

Dr. J. GORDON SHARP read a short paper on the Vital Principles of Foodstuffs, with special reference to their employment in treatment. He said that he thought there might be something in Funk's statement that he had discovered a pyrimidine-like body which was related to thymine. This body was named "vitamine." Dr. Sharp believed in unboiled milk for children exclusively fed on that fluid, and he warned against the use of all dried milks, and, indeed, against all dried and tinned preparations. He also said it was necessary to guard against the use of foods which had been chilled or frozen for long periods. As remedies, he said, lecithins, glycerophosphates, and the nucleins were of little avail in the treatment of malnutrition, but he said that the crude foodstuffs, such as a mixture of eggs, fat, bone-marrow, and malt extract, did good. He had also great faith in cod-liver oil, and used it in combination with egg (both yolks and whites), and found it useful in all kinds of wasting. Fats had an important action in preventing and curing scurvy, scurvy rickets, and marasmus.—The paper was discussed by Dr. T. CHURTON and Mr. F. H. MAYO.

Mr. A. E. LITTLE read notes on a case of Paratyphoid Fever. The patient, a man aged 38, had a rise of temperature every evening for about two weeks before it reached 104° F., when rose-coloured spots appeared. Widal test for typhoid was negative, but positive for paratyphoid. The case was notified as continued fever on account of the character of the temperature, which came down gradually for four weeks before reaching normal, when there was a relapse, with a rise of temperature for a few days. There were nausea and vomiting occasionally in the early stage of the illness; no diarrhœa; duration of rose-coloured spots was shorter than typhoid. The diagnosis of paratyphoid fever must be made by the agglutination reaction.

The PRESIDENT showed Drawings of the Heart from a case of Patent Ductus Arteriosus.

Mr. R. LAWFORD KNAGGS showed a case of Intractable Vesico-vaginal Fistula following Parturition, in which the left ureter was implanted into the rectum by a sacral operation and the right kidney subsequently removed four and a half years ago. The patient had remained well, but returned to hospital recently suffering from prolapse of the upper and anterior walls of the bladder through the vesico-vaginal opening.

Mr. J. A. COUPLAND showed a specimen of Tuberculous Stricture of the Ileo-cæcal Valve which had produced acute intestinal obstruction. The case was treated by excision of the cæcum, ascending colon, and a portion of the ileum, followed by an end-to-end anastomosis, with a satisfactory result.

Mr. COUPLAND also showed a specimen of a Cystic Appendix which had become adherent to the sigmoid flexure and had given rise to strangulation of a loop of small intestine.

Mr. J. F. DOBSON showed a case of Ankylosis of both Hip-joints in the Flexed Position, following acute suppurative arthritis. A subtrochanteric osteotomy was performed on the left side; on the right side arthroplasty was performed on the lines laid down by Dr. Murphy, with an extremely satisfactory result.

Mr. ALEX. D. SHARP showed a case of Pharyngeal Tuberculosis in a woman aged 34, confined chiefly to the right half the pharynx. There was no clinical evidence of pulmonary phthisis, and only during the last few weeks the upper boundary of the larynx had become involved. Agonising pain on swallowing was relieved by local application of pure lactic acid every third day.

Cases were also shown by Mr. H. COLLINSON, Dr. W. GOUGH, Dr. CHURTON, and Mr. G. CONSTABLE HAYES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Pathology and Treatment of Dropsy in Relation to Colloids.

A MEETING of this section was held on Oct. 31st, Dr. J. O'CARROLL, the President, being in the chair.

Dr. WALTER G. SMITH read a paper upon the Pathology and Treatment of Dropsy in Relation to Colloids, in which he developed some recent views upon the causation and pathology of œdema and dropsical effusions. The chief factors of œdema were these: 1. Vascular—i.e., blood-vessels and lymph-vessels. (*a*) Increased supply or inflow of transudate. (*b*) Obstructed or diminished outflow through (i.) lymphatics; and (ii.) veins and capillaries. 2. Osmotic pressure. 3. Physico-chemical alterations in the blood. 4. Alterations in cell nutrition: (*a*) Blood-vessels and lymph-vessels; (*b*) tissue cells; and (*c*) nervous influences. 5. Turgescence of cells. Special emphasis was laid upon the condition of watery turgescence of cells, and illustrative experiments were shown in favour of the hypothesis of Martin H. Fischer (Cincinnati) that even a very slight degree of, or increase in, acidity leads to turgor of cells. Renal and cardiac dropsy were respectively discussed, mainly from the colloid chemical point of view, and the bearings of this idea upon treatment were pointed out.

The PRESIDENT remarked that the paper was a most valuable one, and rare in the history of the Academy. Referring to the possibility of œdema occurring without any discoverable fault of the kidneys or heart, he directed attention to a form of acute moderate dropsy met with in alcoholic cases without any sign of renal difficulty when examined by ordinary methods. This condition was found to clear up rapidly after a few days' rest. The rarity of œdema in cases of mitral stenosis, and its frequent occurrence in connexion with mitral regurgitation, was a matter of interest. With regard to the evil effect of saline purgatives in Bright's disease, it struck him that possibly it might be that the normal tendency of the kidney to get dropsical itself may be increased by the absorption of the common salt—sulphate of magnesium—which was so often administered in cases of dropsy. He was also struck by the evil effect of normal saline injections in inflammatory conditions, especially in acute pneumonia.

Professor W. H. THOMPSON inquired if all œdema included in the definition meant accumulation of fluid in the tissue spaces. He pointed out that tissue fluid was different from the fluid present in the lymph channels. The inhibition idea was not, he thought, brought home so closely to the circumstances as one would like, and it must be admitted that there were other factors which were potent in causing œdema. Alteration in capillary pressure certainly produced no influence on increase of fluid in tissues, except in the case of the liver. He considered that alteration in the capillary pressure without alteration in the cell walls had no influence in the production of œdema.

Dr. A. R. PARSONS, Dr. W. M. CROFTON, and Dr. H. T. BEWLEY also spoke.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Nov. 7th, Dr. David Ross, the President, being in the chair.—Dr. W. Langdon Brown read a paper on Recent Work on Glycosuria. A case was shown to illustrate the recently described type of renal glycosuria which approached the conditions produced experimentally by phloridzin poisoning—i.e., an undue permeability of the kidney to sugar, while the blood contained less sugar than normal. Apart from the glycosuria the patient showed no symptoms whatever and was increasing in weight. The importance of the internal secretion of the pancreas in carbohydrate metabolism had recently been emphasised by the observation that in the depancreatised dog the heart lost its normal power of utilising sugar. The difficulty of associating the pancreas with the glycosuria in some cases was due to the fact that the pancreatic lesion might not be in an active stage at the time the glycosuria was noted, and examples were given of this. Again, the pancreatic defect might not be absolute, but merely relative, owing to overaction of some antagonistic ductless gland, such as the suprarenal, thyroid, or pituitary. Loewi's adrenalin eye test for pancreatic insufficiency was based on this antagonism, and might enable us to determine whether a given case of glycosuria was due to the pancreas. Organic disease of the suprarenals did not cause glycosuria because it was accompanied by a deficiency of adrenalin, but the use of adrenalin in asthma might produce glycosuria, and the suggestion was made that some cases of high blood pressure with glycosuria in later life might be due to overaction of the suprarenals. Overaction of the thyroid, as in Graves's disease, was frequently accompanied by glycosuria, or at any rate by lowered tolerance for sugar, and the medicinal administration of thyroid extract would not infrequently excite glycosuria. With overaction of the pituitary body such as occurs in the early stages of acromegaly glycosuria was often present, while in the later stages when the posterior lobe of the gland had been destroyed there was a raised tolerance for sugar. A case of arrested acromegaly was shown in support of this, a woman who could consume 256 grammes of dextrose at one time without excreting any. After experimental ablation of the gland subsequent removal of the pancreas would no longer excite glycosuria. Puncture of the fourth ventricle excited glycosuria through irritation of the suprarenal and pituitary body. The clinical equivalent of this was seen in the glycosuria of cerebral hæmorrhage, tumours of the brain, and concussion. In an unconscious person the discovery of glycosuria was no evidence of diabetic coma, unless there was diacetic acid present as well. The conception of glycosuria which held the field to-day was a loss of balance between the internal secretions. In treatment the aim was not simply to find a carbohydrate-free diet, for diabetics could often metabolise some form of carbohydrate, such as potatoes, oatmeal or lævulose, while meat proteins might excite glycosuria mainly by their stimulating effect upon metabolism. Cooked eggs and vegetable proteins did not have this effect. Wheat flour was not well borne, and the greatest difficulty was to find a satisfactory substitute for bread. Pure gluten bread was nearly always badly borne, and it was better to allow a small amount of some ordinary bread or of a gluten bread containing sufficient starch to be palatable. The citrates replace carbohydrates to some extent, as may alcohol, as whisky, 1 oz. per diem. To check the onset of acidosis alkalies should be given, but not of one metal alone, or those not given may be drained from the patient. A mixture of sodium bicarbonate, potassium citrate, calcium lactate, and magnesium carbonate was advised to be given, in dose and frequency in proportion to the condition of the patient. When any increased restrictions of diet were imposed alkalies should be given to protect the patient. In impending coma the bowel should be washed out and 4 per cent. of sodium bicarbonate with 3 per cent. lævulose in a litre of water administered by drop enema.—A general discussion followed.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.—A meeting of this society was held on Oct. 29th, Dr. J. Walton Browne (Belfast) being in the chair.—Mr. C. A. Adair Dighton (Liverpool) read a paper on Some Interesting Cases Treated in a Provincial Clinic. The cases he reported were of cavernous sinus thrombosis, latent cerebellar abscess lighted up by the mastoid operation, osteochondroma of the auricle, labyrinthitis and meningitis following polyp extraction, and symptomless lateral sinus thrombosis.—The paper was discussed by Mr. Charles J. Heath, Dr. Walton Browne, Dr. F. Spicer, Dr. J. Coubro Potter, and Dr. J. Walker Wood.—A paper by Dr. H. D. McCulloch on the Therapeutics of Radio-active Agencies in Disease, with special reference to the Cure of Chronic Nerve Deafness and Deaf-Mutism, which had previously been circulated among the Fellows, was discussed. Dr. McCulloch affirmed priority in the discovery in 1908 of this method of otological treatment, and submitted reasons why the hitherto employed medicinal and mechanical means had failed to remove the underlying cause. He deprecated inflation of the tubes in chronic catarrhal states until resolution had been effected *in situ* by radio-active agencies judiciously employed. Incidentally, he drew attention to the important immunising effect in subacute infections, referring to his previous contributions on that subject and to the amount of corroborative evidence that had since accumulated abroad. He exhibited and described various minute apparatus in the application of radio-active agents, mentioned his gratifying experience in a typical case of Ménière's vertigo, and drew attention to the promise of success this method held out in preventing deaf-mutism, the notes of one case being given. The paper was concluded by a tabulated list of 64 cases of hopeless deafness treated by him in 1911.—Dr. Walton Browne drew attention to a case of oto-sclerosis, reported at the recent International Otological Congress, markedly benefited by radium. In this case the improvement had been maintained.—Mr. Heath congratulated Dr. McCulloch on his interesting and scientific paper.—Dr. Potter required further information as to the selective action of the rays.—Mr. Dighton discussed the paper entirely from the aural point of view, strongly objecting to the statement that this treatment promised success in the prevention of deaf-mutism, as this "was not only misleading, but on the fact of things impossible."—Mr. B. G. Pullin, Dr. Spicer, and Dr. Wood joined in the discussion, the last-named stating that he had seen four of Dr. McCulloch's cases and tested them before and after three months' treatment, and though the hearing had not much improved there was an improvement.—Dr. McCulloch replied.—Mr. Charles Heath gave a demonstration of the Usual Methods of Drainage of Suppurating Ears. He said that a persistent discharge from an ear is uniformly accompanied by disease in the mastoid antrum, no matter whether the discharge escapes through the tense or through Shrapnell's portion of the drumhead. He pointed out (and illustrated his statement by moist specimens, diagrams, and patients) that when discharge escapes through a perforation in Shrapnell's membrane the change of route is due to the fact that the channel leading down to the tympanum, inside the incus, is obstructed by swelling of the mucosa of the inner attic wall, and that if the parts outside the incus (including Prussac's space and Shrapnell's membrane) were not unduly weak and capable of being perforated by the pressure of the pus that complete obstruction and acute mastoiditis would result. He exhibited diagrams of swollen mucous membrane obstructing drainage through the Eustachian tube, the tympanum, the attic, and the aditus, and described the symptoms they each produced. Mr. Heath stated that he had treated a considerable number of cases with perforation in Shrapnell's membrane, and while upon the operating table they all proved to be cases of mastoid disease draining on the outer side of the incus instead of (as usual) inside it; pathologically they were, therefore, not cases of attic disease at all. He asserted that it is only when discharge from the antrum descends inside the incus that it is able to reach the tympanic cavity and escape thence in the usual way through a perforation in the membrana tensa. Mr. Heath referred the Fellows to his article in THE LANCET of April 27th, 1907, where he recorded other cases of this kind which were afterwards exhibited before the British Laryngological and Otological Society.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The autumn meeting of the Northern and Midland Division of this society was held by the courtesy and at the kind invitation of the visiting committee at the Borough Mental Hospital, Leicester, on Oct. 23rd. Dr. J. F. Dixon presided.—Dr. T. Arnold Johnston read a very interesting paper on the Position of Pathology in Mental Hospitals. He referred to the difference in psychological ideas to-day as compared with formerly. He dealt with the relation of the medical superintendent and the medical officers to laboratory and research work, and to the ordinary routine duties of an asylum. He considered that the "incubus of routine" stifled ambition, and thought the medical officer needed encouragement and training to obtain his help in laboratory work, and that the pathological department ought to cover both ordinary sick-room work as well as special mental hospital conditions. There was need of a system of educating and interesting the medical officer; of a series of centres for the higher technical forms of laboratory work; and of an interchange and collating of proved research facts and their application to treatment. Altogether the paper brought forward many interesting and important points.—Remarks followed by Dr. J. F. Dixon, Mr. H. J. Blakesley, Dr. B. Pierce, Dr. C. A. Bryan, and others.—In the absence of Dr. H. D. MacPhail his paper on Some Observations on the Cerebro-spinal Fluid was read by Dr. C. H. G. Lyall. He dealt with the results of an estimation of the amount of albumin in the fluid from a series of cases of various forms of mental disorder. He used 5·5 c.c. of the fluid diluted with an equal quantity of water, the fluid being obtained by lumbar puncture. The amount of albumin present was found to vary within wide limits, the lowest being 0·03 per cent. and the highest 0·3 per cent. General paralysis always showed an increase. He considered the test of value in all classes of mental diseases and had found that the greater the amount dose and frequency in proportion to the condition of the patient. When any increased restrictions of diet were imposed alkalies should be given to protect the patient. In impending coma the bowel should be washed out and 4 per cent. of sodium bicarbonate with 3 per cent. lævulose in a litre of water administered by drop enema.—A general discussion followed.

British Oto-Laryngological Society.—A meeting of this society was held on Oct. 29th, Dr. J. Walton Browne (Belfast) being in the chair.—Mr. C. A. Adair Dighton (Liverpool) read a paper on Some Interesting Cases Treated in a Provincial Clinic. The cases he reported were of cavernous sinus thrombosis, latent cerebellar abscess lighted up by the mastoid operation, osteochondroma of the auricle, labyrinthitis and meningitis following polyp extraction, and symptomless lateral sinus thrombosis.—The paper was discussed by Mr. Charles J. Heath, Dr. Walton Browne, Dr. F. Spicer, Dr. J. Coubro Potter, and Dr. J. Walker Wood.—A paper by Dr. H. D. McCulloch on the Therapeutics of Radio-active Agencies in Disease, with special reference to the Cure of Chronic Nerve Deafness and Deaf-Mutism, which had previously been circulated among the Fellows, was discussed. Dr. McCulloch affirmed priority in the discovery in 1908 of this method of otological treatment, and submitted reasons why the hitherto employed medicinal and mechanical means had failed to remove the underlying cause. He deprecated inflation of the tubes in chronic catarrhal states until resolution had been effected *in situ* by radio-active agencies judiciously employed. Incidentally, he drew attention to the important immunising effect in subacute infections, referring to his previous contributions on that subject and to the amount of corroborative evidence that had since accumulated abroad. He exhibited and described various minute apparatus in the application of radio-active agents, mentioned his gratifying experience in a typical case of Ménière's vertigo, and drew attention to the promise of success this method held out in preventing deaf-mutism, the notes of one case being given. The paper was concluded by a tabulated list of 64 cases of hopeless deafness treated by him in 1911.—Dr. Walton Browne drew attention to a case of oto-sclerosis, reported at the recent International Otological Congress, markedly benefited by radium. In this case the improvement had been maintained.—Mr. Heath congratulated Dr. McCulloch on his interesting and scientific paper.—Dr. Potter required further information as to the selective action of the rays.—Mr. Dighton discussed the paper entirely from the aural point of view, strongly objecting to the statement that this treatment promised success in the prevention of deaf-mutism, as this "was not only misleading, but on the fact of things impossible."—Mr. B. G. Pullin, Dr. Spicer, and Dr. Wood joined in the discussion, the last-named stating that he had seen four of Dr. McCulloch's cases and tested them before and after three months' treatment, and though the hearing had not much improved there was an improvement.—Dr. McCulloch replied.—Mr. Charles Heath gave a demonstration of the Usual Methods of Drainage of Suppurating Ears. He said that a persistent discharge from an ear is uniformly accompanied by disease in the mastoid antrum, no matter whether the discharge escapes through the tense or through Shrapnell's portion of the drumhead. He pointed out (and illustrated his statement by moist specimens, diagrams, and patients) that when discharge escapes through a perforation in Shrapnell's membrane the change of route is due to the fact that the channel leading down to the tympanum, inside the incus, is obstructed by swelling of the mucosa of the inner attic wall, and that if the parts outside the incus (including Prussac's space and Shrapnell's membrane) were not unduly weak and capable of being perforated by the pressure of the pus that complete obstruction and acute mastoiditis would result. He exhibited diagrams of swollen mucous membrane obstructing drainage through the Eustachian tube, the tympanum, the attic, and the aditus, and described the symptoms they each produced. Mr. Heath stated that he had treated a considerable number of cases with perforation in Shrapnell's membrane, and while upon the operating table they all proved to be cases of mastoid disease draining on the outer side of the incus instead of (as usual) inside it; pathologically they were, therefore, not cases of attic disease at all. He asserted that it is only when discharge from the antrum descends inside the incus that it is able to reach the tympanic cavity and escape thence in the usual way through a perforation in the membrana tensa. Mr. Heath referred the Fellows to his article in The Lancet of April 27th, 1907, where he recorded other cases of this kind which were afterwards exhibited before the British Laryngological and Otological Society.

Medico-Psychological Association of Great Britain and Ireland.—The autumn meeting of the Northern and Midland Division of this society was held by the courtesy and at the kind invitation of the visiting committee at the Borough Mental Hospital, Leicester, on Oct. 23rd. Dr. J. F. Dixon presided.—Dr. T. Arnold Johnston read a very interesting paper on the Position of Pathology in Mental Hospitals. He referred to the difference in psychological ideas to-day as compared with formerly. He dealt with the relation of the medical superintendent and the medical officers to laboratory and research work, and to the ordinary routine duties of an asylum. He considered that the "incubus of routine" stifled ambition, and thought the medical officer needed encouragement and training to obtain his help in laboratory work, and that the pathological department ought to cover both ordinary sick-room work as well as special mental hospital conditions. There was need of a system of educating and interesting the medical officer; of a series of centres for the higher technical forms of laboratory work; and of an interchange and collating of proved research facts and their application to treatment. Altogether the paper brought forward many interesting and important points.—Remarks followed by Dr. J. F. Dixon, Mr. H. J. Blakesley, Dr. B. Pierce, Dr. C. A. Bryan, and others.—In the absence of Dr. H. D. MacPhail his paper on Some Observations on the Cerebro-spinal Fluid was read by Dr. C. H. G. Lyall. He dealt with the results of an estimation of the amount of albumin in the fluid from a series of cases of various forms of mental disorder. He used 5·5 c.c. of the fluid diluted with an equal quantity of water, the fluid being obtained by lumbar puncture. The amount of albumin present was found to vary within wide limits, the lowest being 0·03 per cent. and the highest 0·3 per cent. General paralysis always showed an increase. He considered the test of value in all classes of mental diseases and had found that the greater the amount the individual subjects treated of adequately within the space available. We can only refer to some of the conditions described and discussed. Dr. Rolleston alludes to the conception of functional disease of the liver, and points out that while the symptoms formerly ascribed to functional inefficiency of the liver are now capable of explanation by other conditions, such as indigestion, constipation, or auto-intoxication, yet it is probable that this condition may be responsible for many symptoms in view of the complex and many-sided activities of the liver. At the same time, in the present state of our knowledge, its existence is difficult to establish. The condition described by Pick as pericarditic pseudo-cirrhosis of the liver is carefully discussed, and is regarded for all practical purposes as an extreme grade of chronic venous engorgement of the liver in cardiac patients with adherent pericardium.

The difficult subject of the various cirrhoses of the liver is dealt with in an admirable manner, and the account and classification of these conditions are the best with which we are acquainted. After a general discussion of the various classifications proposed, Dr. Rolleston adopts for clinical purposes a broad division into two types—viz., ordinary, or portal, cirrhosis, with a rare sub-variety, pigmentary cirrhosis, and biliary cirrhosis, which is subdivided into hypertrophic biliary cirrhosis and obstructive biliary cirrhosis. The descriptions and discussion of the cirrhoses extend to over 160 pages, and include full accounts of the symptoms, complications, and accidents incidental to these diseases. In connexion with portal cirrhosis it is, as the author remarks, somewhat surprising to find from statistics that hæmatemesis occurs less frequently than jaundice, and that it is recorded in only about one-fourth of all patients dying with a cirrhotic liver. In regard to hypertrophic biliary cirrhosis he gives in his adhesion to the French school, who regard this condition as different clinically and pathologically from portal cirrhosis. He points out that it is distinctly rare, and he believes that cases of ordinary cirrhosis with large livers but without persistent jaundice are frequently mistaken for it. The existence of an obstructive biliary jaundice is carefully discussed in the light of experimental and pathological observations, and the origin of the fibrosis is fully considered. It would appear that there is very little evidence that biliary obstruction *per se* causes cirrhosis. The description of primary malignant growths of the liver is interesting, and a useful classification is given. The condition to which the name of cancer with cirrhosis was formerly applied is critically discussed, and Dr. Rolleston accepts the view formulated by Turnbull and Worthington, that the cirrhosis is the primary change and that a compensatory hyperplasia of liver cells occurs which eventually becomes excessive and atypical and thus develops into carcinoma. He therefore suggests that it should be called primary carcinoma supervening in a cirrhotic liver or cirrhosis maligna or carcinomatosa. The varieties of jaundice and the relation of this symptom to the diseases with which it is associated are fully discussed, and all the newer work upon these questions is incorporated.

Diseases of the gall-bladder and bile ducts are dealt with in the same critical and exhaustive manner as the diseases of the liver itself. The concluding section of the book is devoted to the subject of cholelithiasis. The etiology of this condition is carefully considered, and the varieties of gall-stones, their mode of production, and the symptoms and complications are all fully dealt with.

Dr. Rolleston's book is an admirable work of reference in every sense. It presents all the information obtainable from a very wide experience and an encyclopædic acquaintance with the literature of the subject in a practical, interesting, and readily available manner. In every instance the question of treatment is set forth in full detail, and where alternative methods are available their relative advantages are indicated. We feel confident that it will long remain the standard work of reference upon the subjects of which it treats.

Gonorrhœa in Women.

By CHARLES C. NORRIS, M.D., Instructor in Gynæcology, University of Pennsylvania. With an Introduction by JOHN G. CLARK, M.D., Professor of Gynæcology, University of Pennsylvania. London: W. B. Saunders Co. 1913. Pp. 521. Price 25*s.* net.

THE important rôle which the gonococcus is thought by some gynæcologists to play in the production of pelvic disease in the female is shown by the appearance of this monograph of 521 pages. It is naturally an extremely difficult matter to determine the exact number of patients suffering from gonorrhœa, and especially is this the case with gonorrhœa in the female. The published statistics with regard to the frequency of the disease vary very widely, and in many instances no reliance can be placed upon them, because no bacteriological examination has been carried out. In a number of the cases, moreover, such an examination yields no useful information, as the organism is not found, and yet it may well have been the original cause of the disease.

In the year 1901 a Committee on the Prophylaxis of Venereal Disease in New York considered the matter, and estimated that at that time there were 200,000 venereal patients walking the streets of New York. In 36 dispensaries and charitable institutions 14,649 cases of gonorrhœa were treated during the year, but this does not include a number of cases of complications, such as cystitis, venereal warts, and ophthalmia. It has been stated that 80 per cent. of all men in large cities have had gonorrhœa one or more times, that 45 per cent. infect their wives, that 80 per cent. of all operations upon women for disease of the uterus and adnexa are caused by gonorrhœa, and that 20 per cent. of all cases of blindness result from the same cause. Of about 12,000,000 people insured in Germany some 750,000 are annually infected with venereal disease. The author quotes a table showing that the incidence of venereal disease in the different armies of the world varies from 15 per cent. in the Bavarian army to 196 per cent. in the United States army, and a similar table for the navies shows an incidence-rate varying from 66 per cent. in the German navy to 160 per cent. in the American. These figures, even if they cannot be accepted without cavil, show that gonorrhœa occurs with almost incredible frequency, and it must undoubtedly be the cause of an immense amount of suffering and disability in the female sex.

In the chapter on the bacteriology and pathogenesis of gonorrhœa the author describes the best the individual subjects treated of adequately within the space available. We can only refer to some of the conditions described and discussed. Dr. Rolleston alludes to the conception of functional disease of the liver, and points out that while the symptoms formerly ascribed to functional inefficiency of the liver are now capable of explanation by other conditions, such as indigestion, constipation, or auto-intoxication, yet it is probable that this condition may be responsible for many symptoms in view of the complex and many-sided activities of the liver. At the same time, in the present state of our knowledge, its existence is difficult to establish. The condition described by Pick as pericarditic pseudo-cirrhosis of the liver is carefully discussed, and is regarded for all practical purposes as an extreme grade of chronic venous engorgement of the liver in cardiac patients with adherent pericardium.

The difficult subject of the various cirrhoses of the liver is dealt with in an admirable manner, and the account and classification of these conditions are the best with which we are acquainted. Dr. Rolleston's book is an admirable work of reference in every sense. It presents all the information obtainable from a very wide experience and an encyclopædic acquaintance with the literature of the subject in a practical, interesting, and readily available manner. In every instance the question of treatment is set forth in full detail, and where alternative methods are available their relative advantages are indicated. We feel confident that it will long remain the standard work of reference upon the subjects of which it treats.

Gonorrhœa in Women.

By CHARLES C. NORRIS, M.D., Instructor in Gynæcology, University of Pennsylvania. With an Introduction by JOHN G. CLARK, M.D., Professor of Gynæcology, University of Pennsylvania. London: W. B. Saunders Co. 1913. Pp. 521. Price 25*s.* net.

THE important rôle which the gonococcus is thought by some gynæcologists to play in the production of pelvic disease in the female is shown by the appearance of this monograph of 521 pages. It is naturally an extremely difficult matter to determine the exact number of patients suffering from gonorrhœa, and especially is this the case with gonorrhœa in the female. The published statistics with regard to the frequency of the disease vary very widely, and in many instances no reliance can be placed upon them, because no bacteriological examination has been carried out. In a number of the cases, moreover, such an examination yields no useful information, as the organism is not found, and yet it may well have been the original cause of the disease.

In the year 1901 a Committee on the Prophylaxis of Venereal Disease in New York considered the matter, and estimated that at that time there were 200,000 venereal patients walking the streets of New York. In 36 dispensaries and charitable institutions 14,649 cases of gonorrhœa were treated during the year, but this does not include a number of cases of complications, such as cystitis, venereal warts, and ophthalmia. It has been stated that 80 per cent. of all men in large cities have had gonorrhœa one or more times, that 45 per cent. infect their wives, that 80 per cent. of all operations upon women for disease of the uterus and adnexa are caused by gonorrhœa, and that 20 per cent. of all cases of blindness result from the same cause. Of about 12,000,000 people insured in Germany some 750,000 are annually infected with venereal disease. The author quotes a table showing that the incidence of venereal disease in the different armies of the world varies from 15 per cent. in the Bavarian army to 196 per cent. in the United States army, and a similar table for the navies shows an incidence-rate varying from 66 per cent. in the German navy to 160 per cent. in the American. These figures, even if they cannot be accepted without cavil, show that gonorrhœa occurs with almost incredible frequency, and it must undoubtedly be the cause of an immense amount of suffering and disability in the female sex.

In the chapter on the bacteriology and pathogenesis of gonorrhœa the author describes the best and wives being included in the row. It is thus far from easy to tell at a glance which particular group of individuals belongs to each particular sibship. This is perhaps rather a trifling objection, as there is no real ambiguity. There are a few slight errors in the plates; of these some, but not all, are referred to in the list of corrigenda at the beginning of the volume. The absence of the reference number of one diagram on Plate LIV. appears to have escaped the attention of the authors. We draw attention to this because the pedigree is of rather special interest, as it shows a family in which albinism appears to have been latent for eight generations and then to have appeared in three individuals of one sibship. Besides the descriptions of the plates the text contains the bibliography of the monograph with its 700 entries. To some of these a brief note has been appended describing the relevant contents of the work referred to. We understand that the material collected in Part II. is to be statistically reduced and analysed in Part III.

It is a sad reflection that one of the authors, the late Mr. Edward Nettleship, should have died before the issue of the complete work. His great attainments and industry are a distinct loss to scientific work in elucidation of the problems of heredity.

Clinical Laboratory Methods: A Manual of Technique and Morphology designed for the Use of Students and Practitioners of Medicine.

By ROGER SYLVESTER MORRIS, A.B., M.D., Associate Professor of Medicine in Washington University, St. Louis. London and New York: D. Appleton and Co. 1913. Pp. 343. Price 12*s.* 6*d.* net.

THE number of problems on which the clinical laboratory is called upon to aid the physician or surgeon becomes greater every year, and as no one can carry all the details of the necessary procedures in his head continual reference is needed to a library of books dealing with chemistry, histology, and biology.

In the volume before us Dr. Morris has collected together the methods of examination most often called for, and has thus performed a most useful service to all clinical pathologists and to the students of medicine who work in their laboratories. The book deals first with the examination of the urine, setting forth the methods of identifying and measuring the various substances which may be contained in it—salt, albuminoids, pigments, ferments, and parasites—as well as describing the method of estimating the functional condition of the kidneys by the phthalein test. The gastric juice is next dealt with, the various test-meals being described, as also the procedures needed for investigating the stomach-contents when withdrawn; and the examination of the fæces is similarly se
Methods are here included for making per
preparations of the intestinal worms. Chapt
deals with the sputum and Chapter V. with
blood, the concluding section being devoted
puncture fluids, including the cerebro-spinal fluid, in connexion with which the Wassermann test is described. Practical directions are given throughout for the performance of the different methods, the author's own knowledge of the matters with which he deals being evident, and references being frequently given to original articles in which the different methods were first described. There are a certain number of illustrations, chiefly of rarer objects such as animal parasites, but also of apparatus: they might perhaps have been more numerous with advantage.

We warmly recommend the book to those for whom it is intended.

Le Problème Physiologique du Sommeil.

Par HENRI PIÉRON, Directeur du Laboratoire de Psychologie Physiologique de la Sorbonne. Paris: Masson and Co. 1913. Pp. 520. Price 10 francs.

THE physiological problem of sleep is a subject on which countless minds have worked, not always with conspicuous discrimination or success, ever since man turned his attention inwards on the problems of his own organism. Physiologists and psychologists alike have propounded hypothesis on hypothesis, till probably more have been forgotten than are remembered; but we do not think that the difficulties in the way of its solution have been more clearly grasped, or an attempt towards that solution more lucidly expressed or more carefully worked out, than in the present memoir, which represents the researches of some 12 years.

The author remarks that it would be impossible now to propound a theory of sleep for which priority would not be claimed, even by "une voix d'outre-tombe," but he asserts with equal confidence that the facts on which such hypotheses should be based are conspicuous by their poverty. He has therefore devoted many years of experimental work to a determination of the actual factors involved in the oncoming of normal sleep, work based on a study both of human sleep and of the sleep of animals. The t is

Whatever may be the outcome of subsequent investigation, Dr. Piéron's book will take its place as one of the most scientific contributions to the study of the problem of sleep that have appeared in any language.

Der Blutdruck des Menschen: Ergebnisse der Tonometrie.

Von Dr. ARTHUR HORNER, Assistent der I. Medizin. Abtheilung des K.K. Allgem. Krankenhauses in Wien. Mit einem Vorwort von Professor Dr. J. PAL. 7 Abbildungen in Text. Wien und Leipzig: Moritz Perles. 1913. Pp. 198. Price 6 kronen.

Professor Pal explains that the author in his monograph has incorporated not only his own observations, but he had the use of the rich supply of material collected by Professor Pal himself during many years. After a short physiological introduction the author in the first or general part describes the "indirect" methods of estimating the blood pressure for clinical purposes, and in the second or special part he considers fully the variations of the blood pressures in a whole series of affections, such as infective diseases, diseases of the blood, circulation, abdominal viscera, in gynæcological and allied cases, nervous and surgical diseases, and many others. The illustrations leave something to be desired, both in execution and in number. The literature alone occupies 24 pages. The monograph is a most useful compendium as well as a storehouse of new observations on the blood pressure in man.

General Paresis.

By Professor EMIL KRAEPELIN, of Munich. Authorised English translation by J W. MOORE, M.D. New York: Journal of Nervous and Mental Disease Publishing Company. 1913. Pp. 200. Price $3 00.

THE present volume consists of the chapter on general paralysis from Professor Kraepelin's "Text-book of Psychiatry" rendered into English. For this purpose it has been subdivided into seven chapters on the general symptomatology, clinical forms, post-mortem findings, etiology, nature of the disease, diagnosis, and treatment. It contains a full and readable account of the manifestations of the affection, and constitutes one of the most complete descriptions of general paralysis that can be found in any language.

Professor Kraepelin considers that tabes and general paralysis must be regarded as quite distinct, although the arguments which he advances are not convincing. There is no reference to the occurrence of the spirochæta in the cerebral tissues of general paralysis; it might have been inserted in a footnote by the translator, but possibly there was no opportunity for doing this. But all recent advances from the serological and other standpoints are fully dealt with. The translation is on the whole well done.

A Treatise on Materia Medica and Therapeutics, including Pharmacy, Dispensing, Pharmacology, and Administration of Drugs.

By RAKHALDAS GHOSH, L.M.S, Calcutta University, Lecturer on Materia Medica, Calcutta Medical School. Edited by D. H. DEARE, Lieutenant-Colonel, I.M.S. Professor of Materia Medica and Therapeutics, Medical College of Bengal. Fifth edition Calcutta: Hilton and Co. 1913. Pp. 742. Price Rs. 5, or 7*s.* 6*d.*

IN our review of the fourth edition of this work (THE LANCET, March 18th, 1911, p. 745) we fully explained its nature and scope, and expressed the favourable opinion we had formed of it. The present issue has been ably edited by Lieutenant-Colonel Deare, I.M.S., and in the preface he acknowledges the valuable assistance he has had from Dr. B. N. Ghosh, the son of the author.

This edition has been brought up to date, and special interest attaches to the last two sections of the book dealing respectively with serum therapeutics and with organotherapy. Shiga's anti-dysenteric serum is discussed. Shiga claimed that by its use he had reduced the mortality from bacillary dysentery in Japan from 35 *per cent.* to 9 per cent., but in this work it is said that the experience of other observers does not support this statement. An adverse opinion is also given of the value of Yersin's antiplague serum.

The book is very conveniently arranged, especially for reference, and we believe that it will be found useful not only by Indian students and practitioners, but also by Colonial practitioners.

LIBRARY TABLE.

Le Radium: Son Emploi dans le Traitement du Cancer, des Angiomes, Chéloïdes, Tuberculoses Locales, et d'autres Affections. Par LOUIS WICKHAM et PAUL DEGRAIS. Paris: J. B. Baillière et Fils. 1913. Pp. 96. Price 1.50 francs.—*Radium as Employed in the Treatment of Cancer, Angiomata, Keloids, Local Tuberculoses, and other Affections.* By LOUIS WICKHAM and PAUL DEGRAIS. Translated by A. and A. G. BATEMAN, M.B., C.M. Aberd. London: Adlard and Son. Pp. 111. Price 2*s.* 6*d.* net.—The general idea of this small volume can best be described by quoting from the introduction: "What exactly is radium? Which are the diseases in which radium therapy can be useful? To what extent is radium useful in the treatment of cancer? These are the questions which are often asked at the present time, and which we propose to answer by the physical and medical facts within our experience. This work will be limited to a short exposition of the clinical properties of radium, and to a rapid survey of the researches and therapeutic results to which we have specially directed our greatest efforts." It will be seen that the book is not intended for those who specialise in radium, but rather for those who wish for an answer to the questions stated above. Consequently methods and technicalities are omitted; the physical aspect of the subject is stated briefly, but at sufficient length, and the main part of the book is devoted to an account of the diseases—notably cancer—in which the authors have had some success with radium treatment. Many very interesting cases are recorded, and a large proportion of these are illustrated, showing the condition both before and after radium treatment. Considering the great interest in radium at the present time, this book should meet with approval from a large number of the medical profession and not a few of the public. With regard to the English edition, we congratulate the translators on the pleasing way in which they have performed their task.

First Principles of Hygiene. By W. D. STURROCK, D.M. Oxon. Oxford: Clarendon Press. 1913. Pp. 256. Price 2*s.* 6*d.*—In this small volume Dr. Sturrock has presented very clearly a great deal of useful information on matters of personal, public, and domestic hygiene, subjects which he has throughout the book treated as far as possible as questions of applied physiology, and has incorporated with and wives being included in the row. It is thus far from easy to tell at a glance which particular group of individuals belongs to each particular sibship. This is perhaps rather a trifling objection, as there is no real ambiguity. There are a few slight errors in the plates; of these some, but not all, are referred to in the list of corrigenda at the beginning of the volume. The absence of the reference number of one diagram on Plate LIV. appears to have escaped the attention of the authors. We draw attention to this because the pedigree is of rather special interest, as it shows a family in which albinism appears to have been latent for eight generations and then to have appeared in three individuals of one sibship. Besides the descriptions of the plates the text contains the bibliography of the monograph with its 700 entries. Le Problème Physiologique du Sommeil.

Par HENRI PIÉRON, Directeur du Laboratoire de Psychologie Physiologique de la Sorbonne. Paris: Masson and Co. 1913. Pp. 520. Price 10 francs

THE physiological problem of sleep is a subject o which countless minds have worked, not alway with conspicuous discrimination or success, eve since man turned his attention inwards on th problems of his own organism. Physiologists an psychologists alike have propounded hypothesis o hypothesis, till probably more have been forgotte than are remembered; but we do not think tha the difficulties in the way of its solution have bee more clearly grasped, or an attempt towards tha solution more lucidly expressed or more carefull worked out, than in the present memoir, whic represents the researches of some 12 years.

The author remarks that it would be impossibl now to propound a theory of sleep for whic priority would not be claimed, even by "une voi d'outre-tombe," but he asserts with equal confidence that the facts on which such hypothese should be based are conspicuous by their povert He has therefore devoted many years of experimental work to a determination of the actua factors involved in the oncoming of normal slee work based on a study both of human sleep and o the sleep of animals. The psychological aspect i left on one side, and attention is concentrated o the physiological phenomena, respiratory, circulatory, and sensori-motor, accompanying sleep Valuable analogies are drawn from the pathologica conditions of narcolepsy, lethargy, and somnolence and from coma and comatose states. The hibernation of animals is also fully discussed. An elaborat description is next furnished of the physiologica and histological modifications produced in animal experimentally deprived of normal sleep, and it i shown that during the artificial prolongation of th waking life a "hypnotoxin" develops in the seru and cerebro-spinal fluid of the animal experimented on. It is further shown that this toxi is not the banal toxin of fatigue; its injectio into normal animals (into the fourth ventricle is followed after some 30 or 40 minutes b an overwhelming and irresistible desire to slee The author shows commendable caution, however, in discussing the mechanism of this hypnotoxic effect. His view, briefly expressed, is tha this hypnotoxin acts by setting free an inhibitor mechanism in cases where sleep is sudden an profound, while in cases of somnolence there i a direct intoxication of cellular elements, thei functional activity being paralysed by a mechanism which is not nervous, but chemical.

The historical chapters on the theories of slee are very interesting and instructive, nor are the without humour. There is no index of subject only one of authors' names; but there is valuable bibliography of some 61 pages, containing we calculate, some 2000 references.

The work is one of notable erudition, and it is a the same time lucid and readable. The autho does not claim finality for his theory; indeed, h goes so far as to say that a toxic theory is no likely to be of universal applicability. Nevertheless, the experimental basis of his theory is high elaborated, and the results are very suggestive

Whatever may be the outcome of subsequent investigation, Dr. Piéron's book will take its place as one of the most scientific contributions to the study of the problem of sleep that have appeared in any language.

Der Blutdruck des Menschen: Ergebnisse der Tonometrie.

Von Dr. ARTHUR HORNER, Assistent der I. Medizin. Abtheilung des K.K. Allgem. Krankenhauses in Wien. Mit einem Vorwort von Professor Dr. J. PAL. 7 Abbildungen in Text. Wien und Leipzig: Moritz Perles. 1913. Pp. 198. Price 6 kronen.

The monograph is a most useful compendium as well as a storehouse of new observations on the blood pressure in man.

General Paresis.

By Professor EMIL KRAEPELIN, of Munich. Authorised English translation by J. W. MOORE, M.D. New York: Journal of Nervous and Mental Disease Publishing Company. 1913. Pp. 200. Price $3.00.

THE present volume consists of the chapter on general paralysis from Professor Kraepelin's "Textbook of Psychiatry" rendered into English. For this purpose it has been subdivided into seven chapters on the general symptomatology, clinical forms, post-mortem findings, etiology, nature of the disease, diagnosis, and treatment. It contains a full and readable account of the manifestations of the affection, and constitutes one of the most complete descriptions of general paralysis that can be found in any language.

Professor Kraepelin considers that tabes and [illegible] be regarded as quite distinct, [illegible] which he advances are not [illegible] reference to the occurrence of the spirochæta in the cerebral tissues of general paralysis; it might have been inserted in a footnote by the translator, but possibly there was no opportunity for doing this. But all recent advances from the serological and other standpoints are fully dealt with. The translation is on the whole well done.

A Treatise on Materia Medica and Therapeutics, including Pharmacy, Dispensing, Pharmacology, and Administration of Drugs.

By RAKHALDAS GHOSH, L.M.S., Calcutta University, Lecturer on Materia Medica, Calcutta Medical School. Edited by D. H. DEARE, Lieutenant-Colonel, I.M.S., Professor of Materia Medica and Therapeutics, Medical College of Bengal. Fifth edition. Calcutta: Hilton and Co. 1913. Pp. 742. Price Rs. 5, or 7*s.* 6*d.*

IN our review of the fourth edition of this work (THE LANCET, March 18th, 1911, p. 745) we fully explained its nature and scope, and expressed the favourable opinion we had formed of it. The present issue has been ably edited by Lieutenant-Colonel Deare, I.M.S., and in the preface he acknowledges the valuable assistance he has had from Dr. B. N. Ghosh, the son of the author.

This edition has been brought up to date, and special interest attaches to the last two sections of the book dealing respectively with serum therapeutics and with [illegible] anti-dysenteric serum is [illegible] that by its use he had [illegible] from bacillary dysentery in Japan from 35 per cent. to 9 per cent., but in this work it is said that the experience of other observers does not support this statement. An adverse opinion is also given of the value of Yersin's antiplague serum.

The book is very conveniently arranged, especially for reference, and we believe that it will be found useful not only by Indian students and practitioners, but also by Colonial practitioners.

LIBRARY TABLE.

Le Radium: Son Emploi dans le Traitement du Cancer, des Angiomes, Chéloïdes, Tuberculoses Locales, et d'autres Affections. Par LOUIS WICKHAM et PAUL DEGRAIS. Paris: J. B. Baillière et Fils. 1913. Pp. 96. Price 1.50 francs.—*Radium as Employed in the Treatment of Cancer, Angiomata, Keloids, Local Tuberculoses, and other Affections.* By LOUIS WICKHAM and PAUL DEGRAIS. Translated by A. and A. G. BATEMAN, M.B., C.M. Aberd. London: Adlard and Son. Pp. 111. Price 2*s.* 6*d.* net.—The general idea of this small volume can best be described by quoting from the introduction: "What exactly is radium? Which are the diseases in which radium therapy can be useful? To what extent is radium useful in the treatment of cancer? These are the questions which are often asked at the present time, and which we propose to answer by the physical and medical facts within our experience. This work will be limited to a short exposition of the clinical properties of radium, and to a rapid survey of the researches and therapeutic results to which we have specially directed our greatest efforts." It will be seen that the book is not intended for those who specialise in radium, but rather for those who wish for an answer to the questions stated above. Consequently methods and technicalities are omitted; the physical aspect of the subject is stated briefly, but at sufficient length, and the main part of the book is devoted to an account of the diseases—notably cancer—in which the authors have had some success with radium treatment. Many very interesting cases are recorded, and a large proportion of these are illustrated, showing the condition both before and after radium treatment. Considering the great interest in radium at the present time, this book should meet with approval from a large number of the medical profession and not a few of the public. With regard to the English edition, we congratulate the translators on the pleasing way in which they have performed their task.

First Principles of Hygiene. By W. D. STURROCK, D.M. Oxon. Oxford: Clarendon Press. 1913. Pp. 256. Price 2*s.* 6*d.*—In this small volume Dr. Sturrock has presented very clearly a great deal of useful information on matters of personal, public, and domestic hygiene, subjects which he has throughout the book treated as far as possible as questions of applied physiology, and has incorporated with elementary accounts of the bodily functions which may be affected by the hygienic measures discussed. The result is a very readable book which should be useful particularly to nurses, school teachers, social workers, and others who wish to obtain a working acquaintance with the principal doctrines and practices of sanitary science at the present day, and the reasons for their adoption. The facts and theories of hygiene which Dr. Sturrock gives are well and accurately presented. We may, however, take exception to his statement that in milk the fat should in any case come to 2·5 per cent. by weight. The official standard of fat below which adulteration is to be presumed in the absence of evidence to the contrary is 3 per cent., and this is usually regarded as a distinctly low limit. As in nearly all other works on hygiene, the author cannot refrain from describing and illustrating the D-trap, a contrivance which the most experienced sanitary inspector rarely sees outside a museum.

The Ophthalmic Year Book. Vol. IX. Containing a Digest of the Literature of Ophthalmology for the Years 1911 and 1912. Edited by EDWARD JACKSON, M.D., Professor of Ophthalmology in the University of Colorado. Illustrated. Denver: Herrick Book and Stationery Company. 1913. Pp. 518.—The Ophthalmic Year Book for 1911 and 1912 is well up to the standard we have been led to expect. The enormous labour involved in such productions is usually but scantily acknowledged by the support afforded to them, but the gratitude of those who find reason to use them is perhaps some reward. We notice that this publication depends upon the assistance of the Knapp Testimonial Fund of the American Medical Association. This is not as it should be, and we hope that better support will be accorded in the future. The Ophthalmic Year Book has only one serious rival—viz., Nagel's Jahresbericht für Augenheilkunde. We cannot say that it reaches the high standard attained by the German work, but the latter has two great drawbacks: its utility is limited to those who read German, and its publication is usually delayed till about two years after the date of the literature reviewed. On the other hand, English, and especially American, ophthalmic literature receives in the work under review a fuller measure of consideration, so that we have here a valuable link with our confrères across the Atlantic.

Handbook of Information regarding the Routine Procedure of the Division of Communicable Diseases, 1913. By J. S. BILLINGS, Jr., M.D., Chief of Division, Department of Health, City of New York. Published by the Department of Health, City of New York. Pp. 200.—This little work, besides fulfilling its aim of giving information to the medical profession of the City of New York and other parties concerned in the routine of matters relating to communicable diseases, will be of interest to students of comparative sanitation. Besides local information and ordinary routine administration in cases of communicable diseases as affecting the medical profession, institutions, hotel keepers, house owners, and the public generally, it deals in detail with tuberculosis, typhoid, cerebro-spinal meningitis, acute poliomyelitis, malarial fever, puerperal septicæmia, erysipelas, pneumonia, diphtheria, venereal diseases, glanders, and so forth. The technique of the various tests used is described. The sections on typhoid fever and venereal diseases are new. The method of through and through binding with metallic wire impairs the convenience of the book, as it requires a forcible effort with both hands to keep it open.

La Transplantation Restauratrice du Péroné après les Résections des Os Longs du Membre Supérieur pour Ostéo-sarcomes. Par le Dr. HENRY FAY, de la Faculté de Médecine de Paris; Interne de l'Hôpital Saint-Joseph de Paris. Paris: A. Maloine. 1912. Pp. 140.—This pamphlet is decidedly above the average inaugural thesis, indeed it is a real addition to surgical literature. The tendency at the present time is entirely to excise a portion of a bone for sarcoma rather than to amputate; but the limb from which a large portion of a bone has been taken is rendered almost useless unless the damaged bone can be replaced. The fibula seems to offer itself for this purpose, as it may be removed from its natural site without any impairment of function, at least in adults. This treatise deals with the application of portions of the fibula to replace parts of the humerus which have been removed on account of the presence of malignant growths. Ten cases are recorded in which this operation has been performed, and a number of skiagrams taken after the operation show the good results obtained.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XLVII., Nos. 1 and 2. Cambridge University Press. Pp. 1–148. Price 9s. —On the Production and Utilisation of Glycogen in Normal and Diabetic Animals, by E. W. H. Cruickshank. Minkowski in 1892 showed that after complete extirpation of the pancreas, in addition to glycosuria, there was a rapid disappearance of glycogen from the liver; even on the second day after the operation the liver was practically glycogen-free. The administration of glucose did not give rise to any accumulation of glycogen, while the administration of lævulose caused glycogen to appear in the liver. The author experimented on female dogs from 5 to 10 kgm. in weight. Depancreatisation was performed by Hédon's method. Details are given as to the method of estimating the glycogen in the liver and in the normal and diabetic heart. The author confirms Minkowski's observation as to the almost complete disappearance of glycogen from the liver, which becomes loaded with fat. The latter's results with lævulose feeding the author was unable to confirm. Normally the heart muscle contains about 0·5 per cent. of glycogen. Under conditions of increased activity the heart may use up its stored glycogen in a few hours. The diabetic heart contains considerably more glycogen than the normal heart. Activity of the heart evoked by adrenalin rapidly uses up the glycogen. After death, if the normal or diabetic heart be kept warm, glycogen rapidly disappears, due to a glycogenolytic ferment.—The Changes in the Reaction of Growing Organisms to Narcotics, by H. M. Vernon. The author describes the effects of a large number of narcotics—e.g., eight of the monohydric alcohols—esters and ketones. Great changes in the reaction of growing organisms to these and other narcotics were observed, which he suggests were probably for the most part dependent on changes in the composition of the cell lipoids.—The Volume of the "Dead Space" in Breathing, by A. Krogh and J. Lindhard. The authors criticise the results of Douglas and Haldane, who from their experiments concluded that the "dead space" may be increased during muscular work to several times the resting volume. The Danish authors find, however, that the effective dead space in breathing is not appreciably altered during heavy muscular work and that the direct method of determining the composition of the alveolar air from samples taken at the end of inspiration and expiration becomes untrustworthy during muscular work.—The Nature of Thrombin and Antithrombin, by B. J. Collinwood and M. T. MacMahon. The authors used solutions of thrombin obtained by digesting well-washed sheep's fibrin for 24 to 48 hours in 5 per cent. NaCl. This thrombin is destroyed by heat (50—60° C.), acid, alkali, and liquor pancreaticus. Antithrombin, which is present in serum, was used. It is destroyed by heat (60—65° C.), acid, and will only act in an alkaline medium; neutralisation does not destroy it, but only inhibits its activity. The authors suggest that thrombin is a protein, and antithrombin a proteolytic ferment; while fibrin is a combination of thrombin and fibrinogen.—The Ileo-cæcal Sphincter, by Arthur F. Hertz. No mixing takes place under normal conditions between the contents of the small and the large intestines, so that fæcal matter that has once reached the cæcum can never return into the ileum. The sphincter prevents the contents of the ileum passing too rapidly into the cæcum. The author gives an account of some recent observations made with Alan Newton by means of bismuth and X rays.—The Normal Movements of the Colon in Man, by Arthur F. Hertz and Alan Newton. The authors record a series of interesting observations under X rays of six normal individuals whilst they were eating an ordinary dinner between five and seven hours after a bismuth or barium breakfast. On two occasions they observed a large movement of the colon.—The Action of Ions and Lipoids upon the Heart of the Frog, by A. J. Clark. This is a highly technical paper, of interest more especially to pharmacologists. The special apparatus for perfusing and recording the movements of the heart are described. The paper is divided into four parts, of which the first deals with action of kations by altering the ionic content of Ringer's fluid. The authors use the term hypodynamic state to indicate that state of the heart where the frequency remains nearly unaltered but the force of contraction and the rate of conduction are both decreased. The se [illegible] action of anions on the [illegible] third with lipoid substance [illegible] of the heart. The fourth part is occupied with a discussion as to the mode of action of the substances that revive the hypodynamic frog's heart. The summary of results extend to nearly two pages.—W. B. Hardy contributes a short note on Differences in Electrical Potential within the Living Cell.—The Regulation of Respiration and Circulation during the Initial Stages of Muscular Work, by A. Krogh and J. Lindhard, so far as these refer to changes in ventilation, blood flow, pulse-rate, respiratory exchange, and alveolar CO_2 tension. Evidence is brought forward to show that the rise of ventilation, like the increase in heart-rate, is produced not reflexly but by irradiation of impulses from the motor cortex. As to ventilation, these impulses act indirectly through the respiratory centre by suddenly increasing its excitability towards hydrogen ions.—The Carbohydrate Metabolism of the Isolated Heart-lung Preparation, by S. W. Patterson and E. H. Starling. The now well-known heart-lung preparation obtained from dogs rendered completely diabetic by removal of the pancreas 2–7 days beforehand was used. A series of experiments was also made on the consumption of sugar by the isolated lungs in normal and diabetic dogs, serum being perfused. The lungs—normal or diabetic—use up glucose to about 1·3 to 1·5 mgm. glucose per gramme of heart muscle per hour. The figures for the consumption of sugar in normal hearts are extremely variable. Both in the diabetic and the normal heart the authors by the method of comparative blood analysis were unable to arrive at any definite decision as to the consumption of sugar by the heart muscle. If, however, the diabetic heart is over-stimulated with adrenalin, it uses up not only the sugar in the circulatory blood, but also the amount of glycogen previously stored in its substance. The increased utilisation was not due to the lungs. Some of the previous conclusions of the authors as to the beneficial effects of pancreas on the diabetic heart "must be abandoned," or at any rate are susceptible of another explanation. They are inclined as a result of their work "to abandon the view that the essential, or at any rate the primary, factor in diabetes is the absence of power on the part of the tissues to consume sugar."

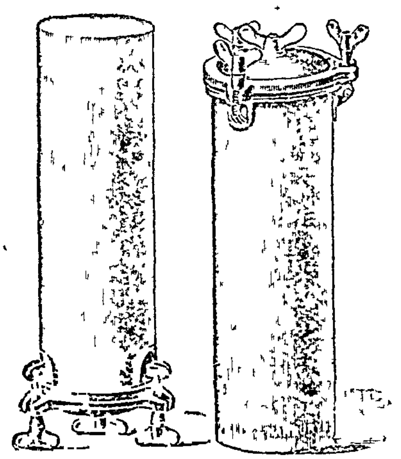
The Quarterly of the Federation of State Medical Boards of the United States. Edited by OTTO V. HUFFMAN. Federation Press, Easton, Pennsylvania. Vol. I. No. 1. October, 1913. Price 50 cents.—The first issue of this publication is naturally mainly of local interest, though a perusal of several of the articles shows not a little that is of interest to all who are especially concerned with the subject of medical education in general. Among these may be mentioned the articles on the Homœopath's View-point of Medical Education, by Dr. Royal J. Copeland; Rules and Regulations Governing Examinations, by Dr. John M. Baldy; Discipline of the Character in Medical Education, by the Hon. Justice Eugene A. Philbin; and Universal Reciprocity, by Dr. Beverley Robinson.

AMERICAN ASSOCIATION OF IMMUNOLOGISTS.—This society was organised on June 15th at Minneapolis, with 41 original members, all of whom have been pupils of Sir Almroth E. Wright, of London. The objects of the society are as follows. To unite the physicians of the United States and Canada who are engaged in the scientific study of immunology and bacterial therapy; to study the problems of immunology, and to promote by its concerted efforts scientific research in this department; and to spread a correct knowledge of vaccine therapy and immunology among general practitioners. The officers temporarily chosen are: Dr. Gerald B. Webb (Colorado Springs), president; Dr. George W. Ross (Toronto), vice-president); Dr. Willard J. Stone (Toledo), treasurer; and Dr. Martin J. Synnott (Montclair), secretary. A council of five members was also selected, whose duty it will be to manage the affairs of the society in the interim of the meetings. This council is made up as follows: Dr. A. Parker Hitchens (Glenolden), chairman; Dr. J. Robinson (Temple, Texas), Dr. Oscar Berghausen (Cincinnati), Dr. Campbell Laidlaw (Ottawa), and Dr. Henry L. Ulrich (Minneapolis). The first annual meeting of the society will be held on June 1st, 1914. This is Monday of the week of the annual session of the American Medical Association, and it will be held at the same place. The programme will be made up of original papers dealing with the different branches of vaccine therapy and immunology.

New Inventions.

A STERILISER-TANK FOR INSTRUMENTS.

I HAVE found the steriliser-tank shown in the illustration very useful when operating in private, as it obviates the trouble and delay which occur when it is necessary to get things ready in the patient's home. This steriliser-tank is a cylindrical vessel 11 in. high and 3½ in. inside diameter, fitted with a lid, which is clamped on by three thumbscrews fixed to lugs which are riveted to the cylinder, like the lid of a high-pressure steriliser. In the centre of the lid is a hole which is closed by a screwing plug. The tank is boiled over a Bunsen or Fletcher burner, the instruments placed inside, and the lid, *with the plug removed*, clamped on. When sufficiently boiled a portion or all of the water is poured off, all that is necessary to do this being to stand the steriliser upside down over a basin; it will rest quite securely on the screws, which act as a stand. When empty, some lysol, spirit, or other solution can be poured through the hole in the lid, the plug screwed in, and the container placed in the bag with the instruments ready to be turned out at the time of the operation, sterilised in readiness for use. When properly screwed up the steriliser-tank is quite water-tight.



The apparatus, which has been made for me by Messrs. Allen and Hanburys, Limited, Wigmore-street, London, W., is of such a size that it will take any ordinary sized instruments required for almost any major operation.

Harley street, W. THOS. NORTH, F.R C.S. Irel.

A PORTABLE X RAY PLANT.

Mr. H. Vogelsberg, a practical electrician, writes as follows:—

"In conjunction with Dr. J. W. Hodgson, of Exmouth, I have designed a portable and self-contained X ray apparatus, the purpose of which is to enable a radiogram to be taken at a patient's residence, and thus save a large amount of unnecessary discomfort or suffering in conveying him to the nearest X ray plant. In time of war it could be used in the open field for examination and location of bullets in the wounded. The car on which the generating plant is erected is a 1906 15-19 h p. four-cylinder Coventry Humber, the flywheel of which is very convenient for driving a dynamo, as it is situated directly under the forward part of the footboards. Three steel T girders are fixed under these boards from the main framework so as to take the weight of the dynamo. When the latter is placed on the car it is raised off a small truck on which it rests when not in use by means of a Weston hoist, and pulled along an overhead rail provided for the purpose in the motor-house until over the position which it has to occupy in the car, and lowered on to its bolts. These bolts can be removed when the car is not required for X ray work. After the car has been driven to the place where it is to be used, the belt is passed round the flywheel and the ends fastened together over the pulley. The dynamo is raised, and the belt made taut by turning round the hand-wheels provided for the purpose, a lock-nut keeping all tight. The dynamo is a continuous current machine, and was supplied by the Cavendish Electrical Company, London. It has an output of 75 volts 12 ampères at 1250 revolutions per minute. The pulley fitted to it is in ratio to the flywheel as one to two; but it would be an advantage to fit a larger pulley on the dynamo shaft, as a steadier speed could more easily be maintained with the engine running faster. The current on leaving the dynamo is carried to the switchboard and passes through the main switch, ampèremetre, and fuse, to the terminals of the switchboard. The mercury interrupter is of the ordinary jet pattern, working in a non-oxidising gas, the gas being carried in a bladder. This type of interrupter has undoubted advantages, but if absolute simplicity is aimed at, one working in oil would be perhaps preferable. The interrupter is worked by a small electric motor, the power for which is brought from the switchboard by means of a flexible wire. Both motor and interrupter are fastened down upon a shallow box which contains the condenser. The advantages of having the interrupter outside the patient's house are twofold: firstly, the elimination of noise; secondly, the man in charge of the motor and plant can look after it and see that it is working properly and well, thus leaving the medical man free. The conductor used for carrying the electricity from the generator to the house is a 7/21 twin cable, carried on a reel in a cable-box. A binding screw is fixed on each end of the real axis, and the inner end of the cable is permanently connected with these, so that only the necessary amount of wire need be unwound, the red end of the axis connected to the interrupter, and from that to the positive pole on the switchboard, and the black end direct to the negative pole. The framework of the couch is made of teak, as light as is possible to be consistent with strength, and can be raised or lowered at one end; the other end can be rested against and fastened by straps to the patient's bed, or can be rested on a trestle. A second switchboard is provided in the patient's room, and stands flat on the ground, a little to the right of the operator, who keeps his foot on a pedal switch. The pedal switch in normal position connects the resistance with the generator; when the pedal is depressed the primary of the coil is connected through the variable resistance. An incandescent pilot lamp gives warning when the current is flowing. The X ray bulb is fixed in a safety case, the inner portion of which is lined with lead oxide. Glass supports are fixed across the openings at each end of the box. An iris diaphragm is fitted over a circular opening on the top of the box, to allow adjustment during the use of the rays. The whole box stands on ball castors, so that it can be moved about under the couch into any position that may be required. The coil used is a Sanax 12 inch intensified coil, which works very well and is free from back currents. Although the apparatus described has not yet arrived at the state of perfection that one would quite wish for, there is reason to suppose that results as satisfactory can be obtained with it as with a fixed plant."

THE SOCIETY OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The annual general meeting of the Fellows and Members will take place at the College, Lincoln's Inn-fields, W.C., on Thursday, Nov. 20th, at 3 P M. Mr. J. Brindley-James, president of the Society of Members, will move this resolution:—

> That this twenty ninth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship, and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation.

Dr. A. S. Morton will move:—

> That this meeting of Fellows and Members requests the Council to include in their next annual report a balance sheet showing fully and without reserve the assets and liabilities of the College on Midsummer Day, 1913.

A resolution calling for the immediate appointment of a special committee, composed equally of nominees of the Council of the College and of the Society of Members, has been sent in but ruled out of order. All communications should be made to Dr. Sidney C. Lawrence, honorary secretary, 22, Latymer-road, Lower Edmonton, N.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 15, 1913.

The Psychology of Railway Accidents.

IN the appalling series of railway disasters which have occurred within the last few weeks in this country and abroad, it is a very striking circumstance that in almost every instance the source of the accident has been traced to a failure in that human factor on which in the ultimate result the proper functioning of even the most ingenious mechanism must depend. These lamentable accidents have been so numerous, and the error or negligence of the driver or the signalman in each case has been so similar in character, that it is difficult to dismiss the suspicion that in this succession of catastrophes we have to deal with something more than a mere casual variation from the normal average of such events; and this suspicion will be strengthened when we take note of the many attendant circumstances which seem to indicate the operation of novel psychological influences, some of them of a more general character than can be explained by temporary conditions affecting a particular industry.

It would, of course, be absurd to found on even a larger number of such instances a general charge of inefficiency and recklessness; and a charge of this sort would be doubly unjust when, as in the present case, it would be urged against a body of public servants whose past record has been so admirable. But without making any such sweeping accusation, it is quite legitimate to inquire whether these instances of negligence may not be related to that ominous change in the mental outlook of the industrial classes of which there have been so many and such grave manifestations in the last few years. The suggestion might seem fanciful, were it not confirmed by the attitude in this connexion of those who claim, and apparently with authority, to speak for the mass of railway workers. The agitation for the release of the Aisgill driver, no less than the ferment excited by the arrest of the man responsible for the disaster to the Paris-Marseilles express, shows with painful clearness that in its latest phase the sense of corporate unity amongst railway servants has become associated with a lessened sense of responsibility towards the community at large. And the same spirit of cynical indifference to the common welfare, the same reckless pursuit of class interest is, of course, the very essence of the syndicalist movement, where the favourite weapon, the general strike, owes what efficacy it possesses to its power to inflict suffering on the public. But it is obvious that the mental attitude which accepts such methods, and which by their acceptance is strengthened and confirmed in its vicious direction, is fundamentally unhealthy and perverted, and by reason of its morbid character must react upon the whole disposition and activity of the individual who adopts it. The temper of syndicalism represents in the group something akin to the temper of paranoia in the insane personality; and just as the self-centred tendency of the persecutory lunatic warps his sense of proportion, makes him too keenly sensitive of his own rights and callous as to the rights of others and the duties which he owes to others, so does the collective paranoia of syndicalism lead to a similar loss of moral balance in the attitude of the given industrial group towards the community of which it should form a part. And this collective spirit naturally influences for evil the individuals who constitute that group; it fosters a state of emotional irritability, of impulsiveness, which is unfavourable to clearness of judgment and accuracy of perception, and which, therefore, might well contribute to such errors and omissions as those responsible for the recent epidemic of disaster. We are bringing no charge of recklessness, and certainly no charge of malice, against particular persons; but we suggest that the conditions of railway travel to-day require most careful attention, and the attention should not be focussed upon the details of this or that catastrophe.

It may not, then, be too fantastic a speculation to connect these sinister occurrences with the spirit of unrest which has pervaded the industrial world of late; and the mere possibility of such an influence should at all events serve as a warning against an attitude of passive acquiescence in the conditions which have brought that spirit into being. These wider aspects of the industrial problem lie outside the scope of this article, nor do they perhaps admit of being so fitly considered from the special point of view which is here adopted. But it may not be out of place to say that in dealing with them we should act on the principle which is the ideal of medical practice, the principle that treatment should be directed to causes rather than to symptoms. If industrial discontent and unrest are contributory causes of inefficiency and recklessness in individual workers, these causes are in their turn the effects of other causes, and it is to the removal of these deeper sources of evil that the efforts of social reform should be directed. And in this task a due consideration of the psychological factors of the problem will be an aid of no small value. Lying beneath most of the varied manifestations of disorder and eccentricity in modern life may be detected as a potent influence the difficulty of nervous adaptation to a too rapidly changing environment. Even the firmest believer in the essential capacity of the race would hardly maintain that human intelligence has progressed in a degree at all commensurate with the development and multiplication of the numerous instruments devised and fashioned by those gifted and subtle intellects, whose discoveries have revolutionised science since the middle of the last century. It is to the new environment of ideas and sensations created by these discoveries, and by their practical applications, that we have to adapt ourselves to-day; and the process, alike for society and for the individual, must at best be slow and arduous, and will inevitably be attended with such occasional failures as find expression in the spread of social and industrial unrest, with an accompanying growth of neuroses.

◆

Insured Persons and Herbalists at Worcester.

WE called attention last week to a decision of the Insurance Committee of the county borough of Worcester which by the vote of a majority, led by the chairman of the committee, decided to allow certain persons desirous of making their own arrangements for medical treatment under the National Insurance Act to do so with a herbalist. We may say at once that we regard the decision as a wrong one, not meaning merely that it is foolish and prejudicial to the insured persons for whose benefit the Act was passed, and for whom it is to provide "against loss of health and for the prevention and cure of sickness," but wrong in law according to every reasonable interpretation of the Act and the regulations made under it. The regulation under which the Worcester Insurance Committee came to the decision referred to orders that:[1] "The committee may allow insured persons resident in the county, whether individually or collectively, in lieu of receiving medical benefit under the regulations made by the committee, to make their own arrangements for receiving treatment (including medicines and appliances);" and the next regulation stipulates that where the committee shall be "of opinion upon such evidence as they think sufficient that the arrangements made by any person who has been required or allowed to make his own arrangements under this regulation are satisfactory—that is to say, such as to secure treatment (including medicines and appliances) not inferior in nature, quality, or extent to that provided under the arrangements made by the committee, and to comply in other respects with any conditions which by reason of any scheme for the distribution of Parliamentary grant must be complied with in the case of treatment provided otherwise, there shall be made towards the cost of that treatment such contribution calculated and paid in such manner as hereinafter in these regulations provided." If the Worcester Insurance Committee is right in considering that the above regulations allow it to spend the funds entrusted to it in paying herbalists or any other unqualified persons who pretend to treat the sick, we say without hesitation that it has discovered a way by which to stultify and reduce to ineffectiveness in particular instances a statute passed "to provide for insurance against loss of health and for the prevention and cure of sickness." We say in particular instances because we are satisfied that the good sense of the community will not allow it to entrust itself as a whole to quacks, Christian Scientists, faith-healers, and bone-setters; but at the same time we believe that one of the general objects for which the Act was passed was to protect or divert, both generally and in particular instances, members of the working classes from the dangers of recourse to unqualified advisers in matters concerning their health.

It may be pointed out that anyone, insured or not, may be treated by whomever he pleases, or by no one. But this is a question of treatment at the expense of the Insurance funds, and if these funds are to be distributed to persons for the express object of their being used to remunerate unqualified persons, there is no reason why druggists should not also be included among those with whom the insured may make their own arrangements. We do not mean to suggest that the registered pharmacists, who are doing such good work under the Act, not always upon highly remunerative terms, would wish to compete with herbalists for patients, but we suggest that they would be as well or better qualified to supply their patients with effective treatment. The matter, however, must depend not upon what the medical profession or the Worcester Insurance Committee or the framers of the Insurance Acts may consider right in principle, but upon what the Acts and the regulations made under it may provide. Obscure reference was made in the recent discussion at Worcester to utterances of a Cabinet Minister in the House of Commons and to dicta of the Insurance Commissioners; these clearly will not affect the question. The regulations from which we have quoted the material words do not say that persons are to be allowed to make their own arrangements for "treatment by duly qualified medical practitioners," or the matter would be beyond argument; they use the term "treatment" without qualification except by the parenthesis ("including medicine and appliances"). Reference to the definitions contained in the regulations from which we have quoted shows that treatment means "medical attendance and treatment of insured persons." Here again there is no direct reference to a "registered" or "duly qualified medical practitioner," but the latter description of those who are to be placed on the panel occurs in the opening words of Section 15 of the Act of 1911. And nowhere, we say with confidence, in the Acts of 1911 and 1913, or in the regulations either of the Insurance Commissioners or of the Board of Trade, is there the smallest reference, or hint or suggestion of a reference, to any kind of treatment being supplied under the Act, or at the expense of the funds provided by it, otherwise than at the hands of those for the testing of whose qualifications and for whose registration the State has provided.

---

[1] National Health Insurance (Administration of Medical Benefit) Regulations, 1912, made under Section 15, Subsection 3, of the National Insurance Act, 1911, which also see.

In this connexion Subsection 4 of Section 15 of the Act is particularly to the point, but we might quote almost any section or regulation referring to medical benefit to the same effect. We need hardly add that every medical certificate purporting to be given under the National Insurance Acts or under any other Acts of Parliament, whether relating to sickness, death, or any other matter, is valueless unless it is given by a registered medical practitioner, and that as a general rule employers, Friendly Societies, and others who require evidence of the sickness or death of individuals in matters not regulated by Acts of Parliament are equally strict in their demands, under the guidance of ordinary prudence and good sense. As to the precise manner in which the question should be raised we are diffident in expressing an opinion, as we do not find the Insurance Acts explicit in providing for the settlement by the Commissioners of disputes between the minority of an Insurance Committee and a majority upon a point of law, as to which the latter is alleged by the former to have taken a wrong view. The Commissioners are, however, certainly interested in the question, because under Section 54 of the Act of 1913 they have to pay out of the National Health Insurance Fund sums required to meet expenditure "properly" incurred by Insurance Committees, and we have little doubt that upon the audit of the Worcester Insurance Committee's accounts the matter could be raised, if not referred directly at the present stage to the Commissioners. There is also the possibility of an application to the courts to prevent the improper expenditure of money by the Committee being the proper course, but we imagine that this would not be necessary unless the Commissioners declined to intervene in an advisory capacity or otherwise. As a result we predict with some confidence that the majority of the Worcester Insurance Committee will find that treatment by a herbalist is not medical treatment within the meaning of the Insurance Acts, whatever may be their personal views as to its being not inferior in nature, quality, and extent to that provided by the medical profession.

Reversion to Type.

THE greater part of THE LANCET this week is printed in larger type than any issue of the journal has ever been, with the exception to be mentioned, the form now adopted being a practical response to representations which have reached us lately from many readers. The larger type now employed, and for the future to be employed, is almost precisely the type in point of size in which THE LANCET made its first appearance one Sunday morning in 1823, and constitutes a reversion as accurate as most of the examples of that phenomenon which from time to time are illustrated in biological articles. Why the Founder of THE LANCET published his first number on a Sunday morning we have not the least idea; but considering the haste in which all the proceedings in connexion with the original issue of THE LANCET were taken, the probability is that the date of appearance was an accident, and that the selection of the original type had no better reason. Only for one year was the paper printed in a type which is just fractionally larger than the one in which this article is printed, for in November, 1824, the type was introduced in which from that date until November, 1913, THE LANCET has made its appearance. During these 90 years the number of representations to us that the size of the type was inconvenient has been, on the whole, not at all large, if we may make this deduction from a personal experience of about a quarter of that period; but the significant fact is that such representations as have reached us have nearly all been made within the last decade, and have certainly increased in number quite recently. There is no doubt now in our minds that our public will find a larger type agreeable and convenient, and we make the change therefore with pleasure, accompanied with a hope that the next revolution in our printing arrangements will, in accordance with precedent, be delayed for another 90 years. For we like to think that such longevity is assured.

From one old member of our staff among those to whom our intentions were mentioned recently, we received a communication suggesting that we were supplying a great example of racial decadence, inasmuch as, if the demands for a larger type to which we were proposing to accede were well founded, it was obvious that the sight of the medical profession at the beginning of the twentieth century was not so good as it had been during a large proportion of the nineteenth century. But we think that this whimsical protest against what he of course called "change for the sake of change" misses the reasons which underlie the desire of our readers for a larger type. If we may draw general lessons in sociology from such a concrete example as the alteration in the printing of a professional newspaper, we would say that we have here one more proof of the great necessity of the times in which we live—namely, the necessity of "speeding up." We telegraph and telephone instead of writing letters; we use machine-driven vehicles on road or rail instead of trusting to our legs or to our horses; and these things not so much to save ourselves trouble as to give ourselves more time in which to take further trouble. We do not recognise any decadence in securing freedom from friction where it can be obtained, when the resulting smoothness is expressed in a larger output of work. THE LANCET in its present guise is easier to read than it has been for 90 years.

Annotations.

"Ne quid nimis."

MINOR EPIDEMICS OF POLIOMYELITIS IN ENGLAND.

WE publish this week two reports of small epidemics of acute poliomyelitis, one of 6 cases in the neighbourhood of Deddington in Oxfordshire, and the other of 8 cases at West Kirby in Cheshire. Both present certain features of interest to which it may be well to direct attention. In the Deddington epidemic, which seems to have followed a somewhat circular route, not unlike what has been observed in one or two of the smaller French epidemics as recorded by Netter, it was apparently impossible to trace any direct contagion, even by the interposition of poliomyelitis carriers, except in 2 cases, and in regard to them the circumstances are not particularly striking. On the other hand, the remark is made that all the cases lived in close proximity to stables. Reference has already been made in the columns of THE LANCET to the experimental work of Anderson and Frost on the transmission of poliomyelitis by means of the stable fly (Stomoxys calcitrans), and it is suggested in connexion with this Deddington epidemic that it originated in infected stomoxys biting the patient whose case is No. 1 in the series. At least one other small epidemic, recorded by Dr. Edwin Bramwell as occurring at Tillicoultry, is known to have been localised in the neighbourhood of farm steadings, and it may well be that these epidemiological facts will serve to throw some light on the spread of the disease in certain localities. At the same time, it must not be forgotten that in the larger epidemics there are innumerable instances of spread of the contagion by totally different methods, and in view of the fact that poliomyelitis is more or less endemic in London it is improbable that its continuance is associated with the presence of the stable fly. However, the interesting features of the Deddington epidemic are worthy of careful consideration. The analogies between the Borna'sche Krankheit of horses and poliomyelitis are, in the present state of our knowledge, scarcely definite enough to lay much stress on. The outbreak of acute poliomyelitis at West Kirby is important inasmuch as the first case occurred last year, in July, as a sporadic or isolated instance of the affection; seven fresh cases occurred in July and August of this year. From what we have learned of the infectivity of the virus and the possibility of its being carried by individuals who do not actually suffer from the disease, there is nothing remarkable in the reawakening of the disease at West Kirby this summer. There is every reason to suppose that the virus lived during the winter in the nasal mucous membrane of one or more individuals related to the primary case. In this epidemic direct infection by contact seems very probable in a number of the cases. Suspicion has fallen on certain vermin—viz., lice—as being perhaps connected with the origin of the disease in the West Kirby series, and where there is still much that is obscure, it behoves the epidemiologist to weigh carefully and without bias the evidence for and against. It has frequently been remarked in connexion with poliomyelitis that domestic animals have been kept in many houses where the disease showed itself. Yet there are just as many instances of the affection in which no association with the presence of domestic pets is demonstrable. Nevertheless, in the West Kirby epidemic the alleged transmission is one to which the attention of those who have the opportunity of experimental investigation will, we trust, be directed. The somewhat curious circumstances surrounding the first appearance of the disease in this district ought not to be forgotten. The documentary value of these two reports is considerable. From small and localised epidemics, as in this Upminster and Tillicoultry instances, much can be learned of significance from the epidemiological viewpoint, and we trust that any other localised groupings of the disease of this summer or autumn will not go unrecorded.

VALLEY FLOODS AND PUBLIC HEALTH.

AN interesting report has recently been presented to the Surrey county council by the consulting medical officer, Dr. Edward C. Seaton, on the Wey Valley Floods in Relation to Public Health. In discussing the influence of floods on health Dr. Seaton remarks that it hardly needs much argument to demonstrate their ill-effect when the dwellings of populous areas are partly submerged, and when the necessaries of life have to be provided for by the help of boats. Even floods of far less magnitude than those which occurred in Nottingham in 1876 and in Norwich last year constitute, he says, not only an acute source of discomfort for the unfortunate residents, but leave behind them the foundation of illnesses of many kinds and often of a chronic nature. Further on he observes that the extent to which ill-health arises is not defined, for there are conditions of the soil which sometimes follow floods and which are liable to become continuing causes of disease. There are, for example, the conditions of the saturation and wetness of the earth upon and near to the surface, which have long been recognised as the underlying causes of illness, either directly or indirectly, sometimes through the medium of insect life. Reference is made to the classical reports of the medical department of the Privy Council upon this subject, and also to a letter written by Dr. R. W. C. Pierce (medical officer of health of Guildford and Woking) to the River Wey Floods Association, in which he drew attention to the remarkable lessons taught by the experiences of the Fen districts of Lincolnshire and Cambridgeshire, where ague was prevalent until a great land drainage system was introduced, when the disease practically disappeared. Instances are also quoted by Dr. Seaton of the salutary effect of building houses above a certain level in districts liable to be flooded by an overflowing river. With these improvements in structure and levels the regional prevalence of phthisis has been lessened. In Leicester, again, the general death-rate has been remarkably reduced since the establishment of a system of drainage which has for some years been held up as a model for other towns similarly situated as regards their levels. Improved drainage is unquestionably an important factor in regard to rendering low-lying places in the neighbourhood of rivers healthy to live in. Much land, says Dr. Seaton, in regions of the valley of the Thames and its tributaries, which is at present uninhabitable, could in time be reclaimed by well-considered comprehensive measures having for their object the unimpeded flow of water right away from its outlet to the tidal river at Teddington Weir during times of threatened floods in its higher reaches. A well-considered scheme on the lines suggested would, in Dr. Sc [illegible] n immense boon to the co [illegible] certain parts of Surrey, [illegible] the means of removing a potent factor in disease. Further, labourers' dwellings should be planned with due regard to health requirements. Dr. Seaton considers that by sufficient drainage of low-lying, damp regions which are at present uninhabitable, these regions would be reclaimed to the public advantage.

THE CONTROL OF MASSAGE AND OTHER ESTABLISHMENTS IN LONDON.

THE Public Control Committee of the London County Council have reported to the Council as to the details of the proposals for the control of massage and similar establishments recently adopted. The subject has been thoroughly discussed in our columns from several aspects.[1] The committee stated that nursing homes were proposed to be included, but added that with regard to the great majority of nursing homes, and many establishments providing the other forms of treatment, there was no suggestion as to their being carried on in any other than a proper manner. It was sometimes alleged that nursing homes were conducted by unqualified persons or with an insufficiently qualified staff; as to this the committee was not in a position to judge. They did not consider it to be the duty of the County Council to interfere in such matters. They felt, however, that the principle of registration was the best one that could be adopted, the right of appeal to a court of summary jurisdiction being given. The report stated that special means must be taken to deal with attempts at evasion by adopting trading descriptions other than those specified by the Council. Furthermore, if the proposed legislation was to be effective severe penalties must, they concluded, be imposed, while all powers obtained ought to be exercised by a central authority. The powers proposed to be acquired by registration are very full. The premises to be registered are to comprise those used as nursing homes or for the purposes of massage or manicure or for administering curative treatment by light, electricity, or baths, or other similar treatment, but all Poor-law institutions, and such hospitals and other premises as may be later defined, are to be exempt from registration. Where the registration authority has reason to believe that the title of a business has been adopted as a cloak to the carrying on of a disorderly house, its officers having a special right of entry, subject to regulations, will proceed to action. The penalties provided are £50 and a daily penalty not exceeding £20 for a first offence, and the same maximum penalties, with or without a term of imprisonment, in respect of a second or subsequent offence. In the case of a company it is provided that proceedings may be taken against all or any of the directors as well as against the company. The committee have also proposed that—

> It shall be an offence for any person or company knowingly to advertise or print or publish an advertisement of any owner or occupier who has been struck off the Register,

a method of action which shows that the source of the evil is properly recognised. The proposals of the Public Control Committee were approved by the Council, and action will follow upon the lines indicated.

THE TRIAL OF BEILISS.

THE Justschinski trial has concluded, with a verdict of acquittal for Beiliss, the Jew accused of murdering a Christian boy for the purpose of obtaining Christian blood for ritual use. A different verdict would have been unthinkable in any civilised country save Russia. But in Russia, and in a leading university town, possessed of all the appurtenances of an advanced civilisation, the barbarous belief that such murders do take place still prevails, and until the very end of the case Beiliss's fate hung in the balance. Indeed, skilled experts seem to have been so affected by the prevailing belief as not to realise that the established medico-legal facts in the case, so far from lending support to the accusation against the accused, failed completely to substantiate any likelihood of a ritual murder. The matter is really brought to a very clear issue in a pamphlet entitled "Der Fall Justschinski,[1] Ofizielle Dokumente und private Gutachten." This pamphlet contains first the following protocols: the post-mortem record of March 2nd, 1911; the second post-mortem record of March 26th, 1912; the report of Professor J. A. Sikorski, of the University of Kieff; Protocol 61, Report of Professor Obolonsky and Prosector Tufanow. The second part consists of the opinions thereon of Professor Haberda, of Vienna; Professor Ziemke, of Kiel; Professor Lacassagne, of Lyons; and Professor Thoinot, of Paris; Mr. A. J. Pepper, Dr. Charles A. Mercier, and Dr. W. H. Willcox, of London; Professor Bleuler, of Zürich; Professor Bonhöffer, of Berlin; Professor Boedeker, of Zehlendorf; Professor A. Forel, of Zürich; Professor Meyer, of Königsberg; and Professors v. Jauregg and Obersteiner, of Vienna. None of these opinions lend any support to the theory of ritual murder put forward with circumstantial detail by Professor Sikorski in a report which is traversed in a lucid and weighty manner. From perusal of this pamphlet it seems to us quite clear that the luckless boy was not killed with any design of securing his blood for any purpose, and was not tortured. The act was probably that of a lunatic.

INACCURACY OF AMERICAN MORTALITY STATISTICS.

A STARTLING article on the inaccuracy of American mortality statistics, written by Dr. Horst Oertel, pathologist to the Russel-Sage Institute of New York, has been sent to us, extracted from a journal called the *American Underwriter*, and its lessons may not unprofitably be taken to heart by some persons in this country who justly fall under Dr. Oertel's censure as dogmatic writers on the statistics of fatal diseases without troubling to test the reliability of the data upon which their statements are founded. "It is strange," says Dr. Oertel, "that, notwithstanding much discussion about improvements in the methods of recording and interpreting these statistics, the reliability of the death certificate itself is generally accepted." He then proceeds to show that the errors and inaccuracies in the present returns of causes of death are so great that it may fairly be doubted whether deductions based on the evidence of American statistics are at all trustworthy. The majority of American death certificates, even those of the larger hospitals, which represent the best available records, are based mainly on bedside diagnosis only. The testimony of American physicians who have systematically performed necropsies appears to be to the effect that the majority of clinical diagnoses are either wrong or quite insufficient to establish the cause of death. From his own experience Dr. Oertel does not hesitate to state that even at the time of the necropsy the medical man is frequently uncertain about the character of the disease and arrives at the truth only after prolonged study. The statistics of Dr. Cabot, of Boston, are instructive in this regard. He has published the percentages of correct diagnoses of what appeared to be the most important lesions revealed by 3000 necropsies in that city, from which it appears that even in the hands of an experienced diagnostician the diagnosis of certain diseases was proved correct in the case of not more than 25 per cent. of the deaths; whilst the percentage did not exceed 75 per cent. in the case of any other fatal disease in the list. Commenting on Dr. Oertel's paper the editor justly remarks that if the actual causes from any considerable proportion of deaths have been incorrectly diagnosed, and the death certificates made out accordingly, the whole structure of a country's mortality statistics fairly totters, and the grouping of classes, ages, and ratios is necessarily subject to the most serious doubts. It is this gravest of dangers in the compilation of American mortality statistics to which Dr. Oertel directs attention, and, in our judgment, the subject is worthy of the serious attention, not of vital statisticians alone, but of all the more important medical societies, medical colleges, and hospital authorities of the country.

ALFRED RUSSEL WALLACE.

THE death of Dr. Alfred Russel Wallace occurred, at the ripe age of 90, on Friday of last week, Nov. 7th. He will for ever be remembered by his association with the great alteration in all our scientific standpoints brought about by the establishment of the modern doctrines of evolution. As is well known, Wallace enunciated the theory of natural selection at the very time when Darwin, after 20 years of solid work, had arrived at similar conclusions, though after more profound and wide-ranging investigations. The attitude of the two philosophers was marked by the greatest generosity to each other; and when the world elected, and elected quite rightly, to give to Darwin the chief credit, Wallace's acknowledgment of the justice of the verdict was complete. The statement that has been made in many places lately that the work of Wallace was put aside and that he himself was unduly neglected does not bear investigation. He was not a candidate for the Fellowship of the Royal Society until quite late in his career, but that body elected him as soon as the usual formalities were complied with, and he was the recipient of one of their most important medals. Wallace was an individual and romantic thinker, but his intuition did not always serve him as well in his attempts to solve other problems as it had when he had jumped at the correct explanation of the processes and changes in organic life. Some of his writings, while they displayed independent judgment, were not marked by the discrimination that might have been expected from so famous a man, and his attitude towards one phase of scientific medicine was unfortunate. But it would be wrong to be blind to the value of grand receptive intelligences like his, because in one or two points the conclusion which Wallace came to appears to us to be hasty. Medicine combines with the scientific world in deploring the loss of a leader, and in acknowledging the debt of the world to a pioneer in the interpretation of the universe.

OCTOBER AT HOME AND ABROAD.

OCTOBER was a very mild month, with a succession of winds from the south and south-west, bringing abundant rain, but occasional clear skies, which allowed the sun to shine for about the average number of hours for the month. October is normally the wettest month of the year in nearly all parts of this country, and generally gives at least one bad wind storm. On this occasion, however, the cyclonic systems either remained on the Atlantic or became reduced in energy on arriving over these islands, and except on some of the most exposed points of the western and northern coasts the wind seldom rose to the strength of a gale. On the ocean to the west a vast area was frequently in a very disturbed condition, some of the storms being very severe, and continuing for days. In England the thermometer was often 5° or 6° above the normal level both during the day and at night, and sometimes the divergence was greater, but as there were a few relatively cool spells, the mean for the whole period was no more than 3° or 4° above the average. At Kew, where the maximum temperature was as high as 60° or higher on 17 afternoons, the mean, 60°, exceeded the average by 4°, while the mean minimum of the night, 46°, was 3° above. At Bath, Torquay, Bournemouth, and Brighton the mean maximum was 61°, and the mean minimum also higher than at Kew, except at Bath. At Torquay and Brighton the figure was 51°, and at Bournemouth 48°. In the Midlands the mean maximum temperature was a little below 60°, and in the north of England, as represented by Harrogate and Buxton, 54°, and the mean minimum 44° or 43°. Paris was warmer than the mainland of this country during the day, recording a mean maximum of 62°, the same figure as Jersey, but at night it was colder, the mean minimum being 45°, no higher than that at Bath. At Brussels the corresponding figures were 61° and 46°, but at Berlin they were lower, the mean maximum of the day only reaching 57°, and the mean minimum of the night being as low as 42°. Over the southern regions of Europe there were few days with a lower temperature than 70°, while in southern Italy the thermometer occasionally exceeded 80°. Round about the 23rd the sheltered thermometer fell to a little below the freezing point in the Midlands and north of England, and to some degrees below it in central Ireland, but no frost was registered at Paris or Brussels, and only one, on the 26th, at Berlin. In most parts of this country there was more or less rain on at least 18 days. In the metropolitan area the total fall was about 3·5 in., exceeding the average by about 0·75 in. Bath had rather less rain, its total of 3·1 in. only exceeding the average by 0·05 in., while at Harrogate there was no more than 2·8 in. against an average half an inch greater. Along the south and south-west coasts there was, as a rule, more rain than in London. At Brighton, where as many as 20 days furnished a measurable amount, the aggregate was 4·2 in., a figure 0·7 in. more than the normal. At Bournemouth it was 3·4 in., at Torquay 3·7 in., or 0·4 in. less than the normal, and at Newquay 5·0 in., or 1·2 in. more than the normal. In the Midlands the fall generally exceeded the average, although in some localities rain was less frequent than in the south and south-west. At Nottingham there were no more than 14 days with rain, against 20 in Brighton and Torquay, but the total fall, 3·64 in., was an inch above the normal. At Buxton, where an average October gives 5·4 in., last month yielded no more than 4·6 in. On the Continent the weather was generally much less rainy than in this country. At Berlin the total fall was 0·6 in., at Brussels 1·4 in., and at Paris 1·8 in. In the southern countries there were a few heavy local falls, but the general character of the weather was dry and bright. In these islands it is now far too late for the total duration of sunshine for the year to equal the average, but last month did its best here and there to make up the deficit, although its best was not very striking. At Kew the total number of hours of bright sunshine was 97, an excess of only 3 hours on the average, but in many places the deficit grew even larger than at the end of September. At Brighton the total of 114 hours was 3 hours less than the normal, and in the Midlands and north of England the weather was mostly less bright than usual. At Nottingham the total sunshine, 76 hours, was 17 below the normal, and at Harrogate, where the figure was 67 hours, it was 28 hours less. On the extreme south-western coast the sky cleared more frequently. At Torquay the sun shone for 113 hours, about the average figure, and at Newquay for 122 hours, an excess of 11 hours on the average. Jersey was brighter than any place farther north, having the good total of 147 hours against an average of 127 hours. Absolutely sunless days were not often experienced in any part of the kingdom. At Kew there were only 4, and in the Midlands 6, 7, or 8, while on the south coast there were only 2 or 3, and at Newquay not one. At Jersey, however, there were 3 sunless days. At Kew the brightest day was the 31st, when the sun shone during seven hours, but over the kingdom generally the maximum amount of sunshine was recorded on various dates—mostly after the 15th. Some places on the south and south-west coasts had between 8 and 9 hours on one day, and a few between 9 and 10 hours. Compared with the south and south-west of these islands and Jersey, Paris was dull. On 5 days the sky was overcast throughout, and the aggregate amount of sunshine for the month was no more than 106 hours, or 41 hours less than at Jersey and 16 less than at Newquay.

THE ANTHRAX COMMITTEE.

AN opportune announcement was made at the close of last week by the Home Secretary that he has appointed a committee of nine to inquire into the dangers from infection by anthrax in the various processes incidental to the wool and hair industry, and to consider and report upon any amendments to the existing regulations which may be desirable. The chairman is Sir Thomas Whittaker, M.P., and the committee contains representatives of the more important interests affected, such as the Bradford Chamber of Commerce, the Bradford Trades and Labour Council, the National Union of Woolsorters, and the Bradford and District Wool Top and Noil Warehousemen's Union. The medical and scientific representation although small, is extremely efficient. It is certain that with Professor F. W. Eurich, of Leeds University, and Dr. T. M. Legge, of the Home Office, upon the committee this side of the inquiry will receive full attention. Professor Eurich, as bacteriologist to the Bradford Anthrax Investigation Board and specialist medical referee to the Home Office for anthrax, has identified himself with the subject under investigation; while Dr. Legge, as one of His Majesty's medical inspectors of factories, has exceptional experience of industrial diseases, and chose as the subject of his Milroy lecture before the Royal College of Physicians of London, in 1905, Industrial Anthrax and Serum Treatment. The secretary to the committee is Mr. G. E. Duckering, of the Home Office, and communications relating to the subject of the inquiry may be addressed to him at 72, Bridge-street, Manchester.

LARGE AMOUNT OF UREA IN THE PERICARDIAL EFFUSION IN BRIGHT'S DISEASE.

THOUGH pericarditis is a well-recognised complication of Bright's disease, the connexion between the two is still disputed. Some writers attribute the pericarditis to toxæmia; others to a superadded infection, usually to a pneumococcic one. In a recent thesis M. André Weill has given the results of the examination of 11 cases. In 2 there was less than 2 grammes of urea in the pericardial fluid, in 6 there were between 2 and 3 grammes, and in 3 more than 3 grammes. Bacteriological examination gave the following results. In 4 cases it was negative; in 2 colonies of the colon bacillus were obtained but the organism was not agglutinated by serum obtained from the patient during life—evidently the infection was agonal; in 1 case there was found a streptococcus and in 4 cases the pneumococcus. At a meeting of the Société Médicale des Hôpitaux of Paris on Oct. 24th M. E. de Massary and M. P. Chatelin reported the following case. A woman, aged 33 years, was admitted into hospital on March 3rd, 1913, complaining of general weakness, cramps in the lower limbs for two months, and dyspnœa. She said she had never previously been ill and had five healthy children. However, two premature labours occurred in 1912, the second at three months on Dec. 27th. Since the end of October she felt fatigued and suffered from pains in the calves and thighs and lost appetite. The miscarriage accentuated this condition. In January, 1913, the legs became a little swollen and the urine was examined and found to contain a large quantity of albumin. She was put on a milk diet but she did not improve, vomiting occurred four or five times a week, and she lost flesh. On examination she was thin, sallow, and pale. The respiration was shallow and irregular (20 to 22 per minute). There was a little œdema, localised exclusively behind the malleoli. The liver was enlarged, and there was a history of alcoholism. At the outer base of the left lung there was slight dulness and crepitation was heard. Some thick mucus was expectorated. The cardiac dulness was enlarged transversely and the apex beat was in the seventh space. A little above it a thrill was felt. At two foci—in the fourth and fifth left intercostal spaces and in the second left intercostal space—marked friction was heard in the form of a rough double sound, which was not transmitted to other parts of the chest and did not exactly coincide with the cardiac pulsations. The pulse was 100, strong, and a little irregular. The urine contained 8·64 grammes of urea and 6·25 grammes of albumin per litre; 500 grammes were passed daily. The arterial tension was 22/14 with Pachon's instrument. The blood serum contained 4·2 grammes of urea per litre. From March 11th to 15th the amount of urine in the 24 hours fell to 300–350 grammes, and the patient vomited and could retain nothing on her stomach. Exploratory puncture at the left base yielded serous fluid. She became somnolent and at times the right eye showed external strabismus. The breath developed an ammoniacal odour. The pericardial friction diminished, but the dulness remained about the same. On March 22nd general convulsions occurred, lasting 10 minutes, during which urine escaped. In the evening she became comatose. Death occurred on the following morning. Soon afterwards 40 to 50 grammes of hæmorrhagic fluid were withdrawn with antiseptic precautions from the pericardium. It contained numerous red corpuscles, some white ones, and patches of desquamated cells. Examination of a film obtained after centrifuging and staining with phenolised thionin did not show any microbes. Also a culture on the serum of the rabbit was negative, as was also inoculation of a mouse. The pericardial fluid contained 6·4 grammes of urea per litre. At the necropsy 90 grammes of hæmorrhagic fluid was found in the pericardium, on which there was a fibrinous deposit. The kidneys were granular and much atrophied; the right weighed 80 and the left 40 grammes. The liver weighed 1300 grammes and was soft and fatty. The lungs were œdematous, and at the left base the tissue was a little more dense and was congested. Sections of the pericardium were examined microscopically for microbes without result. Evidently the pericarditis was due to retention of urea in the system and its accumulation in the pericardium.

ACUTE TYPHLITIS.

SINCE the discovery of appendicitis the term typhlitis has almost disappeared from medical literature, and it is generally held that the cases described by the older writers under this designation were examples of appendicitis. That they were not entirely wrong is shown by the following case of primary acute typhlitis reported in the *Australian Medical Journal* of Sept. 27th by Dr. Geoffrey Owen, who also refers to a very similar case previously recorded in the same journal. He was urgently summoned to a woman, aged 25 years, who had been well till two days previously, when she was seized with abdominal pain and vomiting. At first the pain was referred to the middle of the abdomen, but after 24 hours it became localised in the right lower quadrant. At the end of 12 hours the vomiting ceased. There was no history of previous illness except slight anæmia. On examination she did not look ill. The temperature was 99·2° F., the pulse 88, and the tongue clean. Abdominal respiration was good, but there were definite tenderness and rigidity in the right lower abdomen. The bowels had acted after the administration of castor oil. Acute appendicitis was diagnosed, and though there were no urgent symptoms an operation was advised and was performed next morning. Slightly turbid fluid was found in the peritoneal cavity. Immediately under the peritoneum a mass of omentum was encountered, and on attempting to unravel this it was found to be intimately connected with the bowel and the incision had to be considerably enlarged to make out the condition. The cæcum and part of the ascending colon were found surrounded with omentum, which was glued to them by recent delicate adhesions. The condition of the bowel was remarkable. The cæcum was studded all over with injected vessels, which extended well up the ascending colon. The appendix lay tucked behind the cæcum and was not nearly so injected as the colon. It presented no other sign of disease. The omentum which was wrapped round the large bowel also presented the same curious appearance of acute injection, and in addition was very friable, tearing on the least touch to separate the adhesions. Its terminal part formed œdematous masses. This looked so rotten that it was deemed advisable to ligature off and remove several large pieces. The appendix was removed in the usual manner. Recovery was uneventful. Dr. Owen concludes that the case was one of primary acute typhlitis in which the appendix was only involved in the general process and was not the primary seat of the disease.

MEDICAL TRANSPORT WITH NAVIES.

THE October number of the *Military Surgeon*, an interesting Chicago publication, is mainly filled with articles on the management of the wounded in naval actions. Director-General C. F. Stokes, of the United States Navy, has worked up a scheme which details a "medical transport," a ship of 10,000 tons or more, to each division of the fleet, a division including four battleships with destroyers and auxiliaries. After a battle the medical transport arrives and sends to each of its battleships, or to its destroyers, a section of its boats with a dozen medical officers and sick-berth stewards and four dozen sick-berth attendants. They all get on board the battleship of whatever sort it may be, give what additional attention is required to the wounded, and move these into the boats and take them to the medical transport for conveyance to the base. This scheme was obviously suggested by the field ambulances or bearer companies of the army. It is too elaborate to be of use at sea. In bad weather Director-General Stokes proposes to transfer wounded in cots along an aerial railway, sliding the cots on a wire hawser stretched from the stern of their ship to the bow of the medical transport. A similar method was tried in our navy for coaling ships at sea, but did not give satisfaction. The first essential for the satisfactory care of the wounded in a naval action—namely, that their fleet must be brought out victorious—is forgotten. Extemporised measures will secure a higher percentage of recoveries for the victors than the most elaborately prepared plans can hope to achieve for the vanquished. So it is a serious matter to propose to make arrangements to help the wounded which shall in any way hamper the fighting efficiency of their ship or squadron. Surgeon J. L. Pleadwell's paper on the Relationship of the Hospital Ship to the Fleet in Time of War is most instructive in this connexion. The problems of the medical officer in charge, although so tangled, are very clearly stated and resolved. This thoughtful article should be read by every naval medical officer. A similar remark applies to Captain Lazell's paper on Mental Hygiene, and the improvement of the rank and file in army and navy. The Association of Military Surgeons of the United States, including Army, Navy, and Public Health Services, held its annual meeting at Denver, Colorado, in September, under the presidency of (Fleet) Surgeon W. C. Braisted, United States Navy; and Surgeon-General W. H. Norman, representing the Royal Navy and

Royal Army Medical Services, received a hearty welcome.

A LANTERN lecture will be delivered before the Fellows of the Royal Society of Medicine, in the Robert Barnes Hall, 1, Wimpole-street, on Thursday, Nov. 20th, at 5 o'clock, entitled "The Leprosy Problem in the British Empire, illustrating the Clinical and Bacteriological Aspects of the Disease: with Remarks on the Clinical Aspects of Syphilis among Natives," by Dr. H. Bayon, Research Bacteriologist to the Government of the Union of South Africa.

MEDICINE AND THE LAW.

A Death Certificate Given by an Unqualified Person.

AT the recent Gloucester assizes a prisoner charged under the name of Jose Manuel de Freitas was indicted for having given a certificate of the cause of death not being a medical practitioner, for fraudulent conversion of money entrusted to him for the purchase of surgical instruments by the Cinderford and District Friendly and Medical Aid Association, and also for having obtained £37 by false pretences from the association. It was stated that the prisoner, who pleaded guilty, obtained the post of medical officer of the association mentioned by replying to an advertisement, and carried out his duties for three weeks without complaint from his patients. The association is not to be congratulated upon the success of its efforts to obtain a medical attendant for its members, and it would be interesting to know what steps it took to ascertain the qualifications of the man whom it engaged; for the prisoner, in addition to the fact of his not being a medical practitioner, although he bore, or had assumed, the surname of a gentleman on the Register, was given a very bad character by a detective from Scotland Yard. He was described as a man who lived by fraud and on the immoral earnings of women; he had defrauded a lady of over £1300 and a gentleman of £100, and had also carried on unqualified practice in several localities. He was sentenced by Mr. Justice Coleridge to 10 months' hard labour, which does not seem an excessive penalty.

An Attempt to Blackmail a Medical Man.

At the recent sessions of the Central Criminal Court a man named Gates, a picture framer, 21 years of age, was convicted and sentenced to three years' penal servitude upon an indictment charging him with sending to Dr. W. J. Bell a letter demanding money from him with menaces and without any reasonable or probable cause. The prosecutor, a medical man practising at Peckham, and being upon the panel under the Insurance Acts, attended a girl named Wright at his surgery, where he saw her on four occasions, and afterwards at her father's house, where she was in bed under his orders, and where he paid her six visits. This was before April 28th, after which date and before July 31st the patient paid 23 visits to the prosecutor's surgery. Early in August the prisoner had banns of marriage between himself and Wright published at a local church and fixed the marriage for August 25th. On August 12th a letter was received by Dr. Bell accusing him of improper conduct towards Wright, and threatening that an action claiming £2000 damages would be started unless a settlement by payment of £100 should be made. Dr. Bell wisely took the only right course with promptitude, communicating immediately with his solicitors, and the police arrested Gates and Wright. The latter pleaded guilty, and stated through counsel that she in fact wrote the letter, but that Gates was responsible for the whole of its contents, that there was not a particle of truth in the allegations made in it, but that every suggestion in it came from Gates who had coerced her into copying the document. She was bound over to come up for judgment when called upon. Dr. Bell is to be congratulated upon the conclusion of an episode which must have been a very painful one to him, and upon the successful and complete repudiation of an odious charge which exemplifies the dangers to which the medical practitioner is frequently exposed in the exercise of his profession. It may be mentioned that in his opening speech, after describing the number of attendances required by the illness of Wright (who had suffered from rheumatism), Mr. Bodkin, who appeared for the prosecution, called attention to the thoroughness of the treatment accorded to her under the Insurance Acts.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Treatment of Tuberculosis.

FOR four hours on Nov. 4th the Council debated the Public Health Committee's reports which appeared in THE LANCET of Oct. 25th, p. 1205, and Nov. 8th, p. 1332, with regard to provision for uninsured persons suffering from tuberculosis. Discussion first took place with regard to the recommendation, already published in full, as to the financial basis of the provision for treatment of uninsured persons.

After some debate on the general question, in the course of which it was pointed out that the formulation of a comprehensive scheme for London had been under consideration by the Council ever since the Insurance Act was passed in December, 1911, the following motion was proposed by Mr. RAWSON:—

> That the recommendation be referred back to the committee with instructions to ascertain whether the metropolitan borough councils desire local dispensaries to be under the sole control of the borough councils or the London County Council.

An amendment that steps be taken to arrange another conference with the Local Government Board was lost by 45 votes to 32, and the original motion was then put to the vote and defeated.

Dispensary Provision for Uninsured Persons.

Mr. A. L. LEON moved an amendment to the Public Health Committee's recommendation in the following terms:—

> That the Council, whilst regretting that a scheme has not been made earlier, is of opinion that no scheme for the treatment of tuberculosis in London can be comprehensive or satisfactory while the Council is prevented from dealing with the provision of dispensaries by the premature action of the Local Government Board in approving partial and local schemes in London, and that the Board be asked to cancel all consents given for the erection of dispensaries, and to make an Order enabling the Council itself to provide and administer (itself or through borough councils) all dispensaries required, one-half of the expense to be defrayed out of the county fund as expenditure incurred for general county purposes and one-half to be defrayed by the Government.

Mr. Leon advised the Council, since the Local

Government Board had taken a line which deprived the Council of authority, to wash its hands of dispensaries schemes and confine itself to the provision of sanatoriums. It was a matter for keen regret that the Local Government Board should have allowed a number of dispensaries to be started in different parts of the metropolis without regard to the needs of London as a whole. It would be impossible to coördinate and make available the highest medical skill and knowledge existing if the borough councils were to be the units for dealing with the tuberculosis question. The Public Health Committee had conferred with the authorities of 12 large hospitals; these bodies were very anxious to fall in with a scheme, but they made it an essential that the Council should be the one centralising authority for London. In some boroughs there were no hospitals, and there were cases where a borough council had refused to act with a hospital and *vice versâ*.

Mr. F. BRIANT, who seconded, said he did not wish to be unduly severe on the borough councils, but no more serious blow could be struck at a comprehensive policy than to leave hospitals out of a tuberculosis scheme. The hospitals with medical schools—in fact, the whole of the teaching hospitals—had passed a resolution in which they had emphasised the importance of the administration being in the hands of the London County Council. If the borough councils declined to have anything to do with the hospitals very unsatisfactory results would be obtained. Of 730 people treated at St. Thomas's Hospital dispensary 340 required special surgical treatment, and this was not available at an ordinary tuberculosis dispensary.

Mr. J. A. DAWES, M.P., Chairman of the London Insurance Committee, said that the time for moving the amendment had passed; six months ago it might have been acceptable. The Council ought to have been in possession of the views of the Local Government Board at a much earlier date; the Board had taken a most unfortunate line. Rather than have any more delay the Council had better pass this scheme and try to induce the borough councils to adopt some suitable measures for their respective areas. Nothing could be more unfortunate than to have 29 areas each in a ring fence, but that was what matters had come to. He did not think the hospitals made it an essential condition that the County Council should be the authority; they would try to make the best of a bad job. He did not like this scheme, but in the interests of tuberculous persons it should be adopted. The County Council was still the authority for residential purposes, and this might give it some power; the monetary control was just worth having.

Mr. O. E. WARBURG hoped that it would be possible to secure the coöperation of the hospitals, and that the County Council would be able to maintain a proper balance between dispensaries, hospitals, and local medical officers of health.

The amendment was lost by 34 votes to 20.

Financial Questions.

Debate then took place on the question of equalising the cost of tuberculosis treatment throughout the metropolis so that boroughs where the phthisis rate was high and was accompanied, as would usually be the case, by a low rateable value should receive financial assistance. Amendments to secure this were defeated by considerable majorities.

Mr. GILBERT JOHNSTONE moved an amendment that in view of the fact that the London Insurance Committee had resolved to make representations to the Treasury as to the inadequacy of the sums available for sanatorium benefit in respect of insured persons the Council was of the opinion that no comprehensive scheme could be carried out adequately unless provision were made for meeting the full cost of the treatment of insured persons out of the Insurance Fund or by the Government.

Mr. DAWES pointed out that the only deficit as to which the Insurance Committee made representations was in respect of residential treatment, and the shortage was due to the fact that the British Medical Association had been able to secure the allocation of 6*d.* per head to the doctors for domiciliary treatment. There were sufficient funds to provide for dispensary treatment.

The amendment was carried by 42 votes to 22.

The recommendation as amended was then agreed to in the following form:—

That any comprehensive scheme for dealing with the treatment of tuberculosis in London shall provide for a contribution being made by the Council from year to year towards so much of the cost of the dispensary treatment of uninsured persons in the City of London and each metropolitan borough as would otherwise fall on the local rate, after taking into account the promised grant from the Imperial exchequer, provided that such contribution (1) shall not exceed 50 per cent. of such cost; (2) shall be made in the first instance from a date to be fixed hereafter by the Council; and (3) shall be conditional upon the Council being satisfied with the local scheme in force in such area and upon the arrangements and the expenditure being annually submitted to and approved by the Council. Whilst by the above proposals ample funds will be provided to meet the cost of dispensary treatment for uninsured persons, in view of the fact that the London Insurance Committee has resolved that representations shall be made to the Treasury as to the inadequacy of the sums available for defraying the expenses of sanatorium benefit in respect of insured persons suffering from tuberculosis in the county of London, the Council is of opinion that no comprehensive scheme can be carried out adequately unless provision is made for meeting the full cost of the treatment of insured persons out of the Insurance Fund or by the Government.

Residential Accommodation for Uninsured Persons.

On the report of the Public Health Committee with regard to residential accommodation for uninsured persons and its recommendation that the Council should make arrangements with the Metropolitan Asylums Board, with hospitals and with sanatoriums without the Council owning or managing institutions (see THE LANCET, Nov. 8th, p. 1332).

Major LEVITA moved an amendment to the effect that the Council should not act as a financial intermediary, but should leave it to local health authorities, the Asylums Board, and other bodies to deal with tuberculosis. He criticised the proposed arrangements on the ground that at every stage of the disease except one the borough councils were to deal with tuberculosis; the County Council which had lost control of the scheme as a whole was to come in and deal with one small section of the problem. It would be irritating to the hospitals to find that as long as a man went to a dispensary he was under one set of authorities, but when the disease needed sanatorium treatment he came under another set of authorities. He did not know that the borough councils, which were the proper authorities to deal with health matters, had asked the County Council to make arrangements for residential treatment. It was estimated that 400 beds were required for uninsured persons; the hospitals were not full, and he was not sure that existing institutions could not deal with residential treatment now that the Council at the request of the Insurance Committee had provided for insured persons.

The amendment was lost, only five voting in favour.

The debate continued on the main question on the line that the County Council should not delegate to the Asylums Board the provision of accommodation. Mr. DAWES said that although the Asylums Board had done its best to help the Insurance Committee out of a serious difficulty, the institutions it had provided were not entirely suitable, because it had none of the smaller sanatoriums required. As a matter of fact, the Asylums Board had no more institutions suitable for dealing with tuberculosis than had the County Council.

The committee's recommendation was then agreed to.

The Mount Vernon Hospital, Hampstead.

In regard to the views of the London Insurance Committee and of the Public Health Committee as to the acquisition of this institution (see last issue, p. 1333), Mr. L. COURTAULD, a medical member of the Council, moved an amendment to omit an expression of opinion in favour of the purchase of the institution or a communication to the Asylums Board on the subject so that the motion would read:—

> That the Council is not prepared to purchase the Mount Vernon Hospital, Hampstead.

Mr. Courtauld said the institution was not suitable for any other purpose than hospital treatment of tuberculosis, and it would be unwise, if not impossible, for the Council to enter upon the conduct of a hospital. The institution was unsuited for a sanatorium because it had only 2½ acres of ground and so did not provide opportunities for graduated exercise and labour. It would be too miserable and depressing a place to be used as a home for advanced cases; these should be put in small cottage hospitals rather than in a big institution in which it would be difficult to persuade them to stay. As to the use of Mount Vernon for hospital cases, this would be undesirable because when things had settled down it would probably be found that there was sufficient provision in London for hospital patients. There were vacancies for male patients in the wards of Brompton Hospital, a thing that had not happened for a very long time. The majority of the large teaching hospitals were willing and even anxious to extend the accommodation in their wards for hospital cases. They feared losing material for teaching. The hospitals were the obvious places to which these cases should go, and it was not incumbent on the County Council either to acquire or advise any other body to acquire such an institution as Mount Vernon for the reception of hospital patients. These were difficult and complicated cases requiring special forms of diagnosis and treatment such as could not be obtained in the ordinary sanatorium but only in the large special fully equipped hospitals. It was one thing for the Council to manage a sanatorium which only required a medical superintendent and one or two assistants, but quite another thing to run a special hospital requiring a specialist staff and a large specialist organisation which the Council would have very great difficulty in bringing together, at any rate until municipalisation or nationalisation of hospitals was very much nearer.

Mr. DAWES said that the London Insurance Committee was favoured by having seven medical members who unanimously urged on a deputation to the Public Health Committee that Mount Vernon should be retained as a hospital to accommodate certain classes of cases. With all respect, their opinion should carry more weight than the single opinion of Mr. Courtauld. That large and influential body of medical opinion was very strongly in favour of the acquisition of Mount Vernon. This was one of the four specialist hospitals of London and if it were closed there would be a shortage of accommodation. The Insurance Committee thought this building would be specially valuable because it would be easy for friends to visit patients there.

The amendment was carried by 52 votes to 30, and the recommendation of the Public Health Committee as amended was then approved.

Administration of the Mental Deficiency Act.

The Council debated at considerable length a proposal by the General Purposes Committee that for the purpose of administering the Mental Deficiency Act, 1913, the Asylums Committee be abolished as a statutory committee, and that a new committee be appointed to coördinate the asylums work and the care of the mentally defective under one administration. Persons having special knowledge and experience of the care of defectives would be coöpted, and the Council would have direct control of expenditure, which it has not at present in the case of the Asylums Committee. Members of the Asylums Committee, without distinction of party, protested against the proposal. Several amendments aiming at postponement having been rejected the Council decided by 69 votes to 48 to proceed with the scheme.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

City of Coventry.—The annual reports of medical officers of health are often used to express the individual views of their authors on administrative and scientific questions relating to public health, and this feature adds much value to an annual report. It is, however, sometimes prudent to recollect that these reports are made in the first instance for [illegible] the members of

provision for cases of infectious disease. We meet there the statement in regard to small-pox "that by experience we have learnt that small-pox is, *par excellence*, the disease which can be entirely controlled by isolation and disinfection." Dr. Snell presumably takes vaccination for granted when he makes no mention of it, but it would be better to explain to the layman that the truth of his proposition rests on the necessity of protection by vaccination, or by previous small-pox, of the staff of the hospital, the disinfecting staff, and the contacts of the patient. On the other hand, in referring to plague, Dr. Snell states that "the mere isolation of the patient and disinfection of premises can only be a secondary means of combating infection; the extermination of the rat is the real desideratum." This is an arguable opinion, but when human plague has been introduced into this country, as has now happened on several occasions, it has not necessarily been *rat-borne*, and in the suppression of human plague, should it occur in an English city like Coventry, primary reliance ought to be placed on isolation of the human case and not on attempts to destroy rats. The portion of the report to which we refer sets out with some force objections to "older empirical methods" of isolation and disinfection, and represents that in view of recent research their use must be directed by an intelligent knowledge of individual diseases. This unimpeachable proposition has always lain at the root of epidemiology, a science which is not quite as new as might be inferred from the context of the report. In consequence of the occurrence of some serious cases of ophthalmia neonatorum in Coventry, Dr. Snell, after consultation with Dr. T. Harrison Butler, now endeavours to secure that newly born children, whether they show signs of eye inflammation or not, should have their eyes treated with a 5 per cent. solution of protargol. All practising midwives have been circularised on the subject, and informed that the solution can be obtained from any chemist at a cost of a few pence per ounce. Dr. Snell has reason to think that most of the midwives now adopt this procedure.

Metropolitan Borough of Poplar.—Mr. F. W. Alexander's report illustrates the great variety of useful public work done by his department in this large area of Eastern London. In Poplar great use is made, for disinfecting purposes, of "electrolytic fluid" produced by the electrolysis of a saturated solution of magnesium chloride, to which salt and caustic soda have been added. The cost of production in Poplar is just under £2 per 1000 gallons, and the fluid is used for all ordinary purposes of fluid disinfection, including the cleansing of school premises, and, by a special contrivance, for the treatment of the water in the public swimming baths. The effective and cheap purification of swimming bath water is a most desirable practice. It is said to be adopted in Poplar not with the idea of rendering periodic changes of the water unnecessary, but to keep the bath water fresh and free from harmful organisms all the time it is in use.[1] Mr. Alexander claims, with the support of a committee on the purification of swimming baths which was appointed by the Royal Sanitary Institute, that by supplying one part of free chlorine to every 2 or 3 million parts of water, "not only is the water sterilised or deprived of all organised living molecules, but it is kept sweet and free from odour, and there is no tendency in the water to the deposition of slimy sediments on the floor of the pond." A certain amount of slimy matter collects on the water, but this is readily removed with a swab by the attendant. The "cleansing" of verminous persons is a matter which is often too little considered; there are few operations more useful, and it is satisfactory to find that the borough cleansing station was utilised for over 300 inmates of common lodging-houses in 1912. Some of these came from common lodging-houses outside the borough, the London County Council having arranged for a payment to the borough of 1*s.* per person in such cases. Mr. Alexander publishes a letter from the Local Government Board on the subject of notification of ophthalmia neonatorum, which makes it clear that the official recognition of this term is not limited to purulent ophthalmia caused by the gonococcus, but includes all cases of purulent eye discharge caused by other organisms, when these discharges occur during the first few days after birth. An important prosecution under Section 47 of the Public Health (London) Act took place during the year, which resulted in a decision which overruled a defence that a limited company is immune from prosecution for selling unsound food or exposing it for sale. The decision, however, was on other grounds given against the borough council, which brought the action, not against the retailer of unsound goods, who had surrendered them to the sanitary authority, but against the wholesale dealer from whom the unsound goods had been obtained. The borough council has made representations to the Local Government Board urging that the Public Health Acts should be amended so as to protect the public against the sale of unsound food by wholesale vendors.

Borough of Macclesfield.—In this industrial town, which has a population of about 35,000, and in 1912 a birth-rate of 20·1 per 1000, the rate of infantile mortality is usually high, and last year represented 115 per 1000 births. 37 per cent. of these infantile deaths were attributed to prematurity and congenital debility and defects, and Mr. J. H. Marsh states that the majority of the mothers of these infants had previously had abortions, miscarriages, or premature births, and that about half of them suffered from marked ill-health and poor physique. He considers that further reduction in the infantile mortality rate requires to be made by means of much greater future attention to ante-natal conditions, especially those of underfeeding and overwork. Cleanly surroundings of working-class homes, it is well known, have a marked effect on the epidemic diarrhœa of infants, and in this relation Mr. Marsh gives a useful caution against the conclusion that the replacement of outside privy-ashpits by water-closets is all that is required. The dry dust in such cases is often put into portable bins, with loose covers or none, which are left standing in the backyard, overfull and spilling their contents. Often scavengers cannot get on to the premises at the time of their regular visit, and thus the accumulations are increased. Mr. Marsh's demand that dustbins in the centre of the town should be emptied at least twice a week in the summer months and not less than once a week during the rest of the year seems in no way excessive. Although a high degree of fly prevalence is not necessarily accompanied by a high diarrhœal fatality, there are very strong grounds for associating the two occurrences, and high diarrhœa rates would hardly be surprising in the neighbourhood of some of the large uncovered middens of horse manure in the centre of the town, which Mr. Marsh describes as forming a prolific breeding-ground for these carriers of filth into the homes and food of the people.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns, with populations exceeding 50,000 persons at the last Census and whose aggregate population at the middle of this year is estimated at 17,852,766 persons, 8687 births and 4561 deaths were registered during the week ended Saturday, Nov. 8th. The annual rate of mortality in these towns, which had been 13·6, 13·1, and 13·9 per 1000 in the three preceding weeks, declined to 13·3 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 13·6 per 1000, which was equal to the rate recorded in London during the same period. Among the several towns the death-rate last week ranged from 4·8 in Gillingham, 6·8 in Oxford, 7·6 in Willesden, 7·7 in Newport (Mon.), and 7·9 in Aberdare, to 18·8 in Middlesbrough, 18·9 in Stockton-on-Tees, 20·1 in Great Yarmouth, 20·2 in Dudley, and 24·6 in Barnsley.

The 4561 deaths from all causes were 193 fewer than the number in the previous week, and included 435 which were referred to the principal epidemic diseases, against numbers declining from 925 to 509 in the four preceding weeks. Of these 435 deaths, 261 resulted from infantile diarrhœal diseases, 46 from whooping-cough, 46 from diphtheria, 34 from scarlet fever, 30 from measles, and 18 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·3, against 1·6 and 1·5 per 1000 in the two preceding weeks. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily decreased from 769 to 322 in the four preceding weeks, further declined to 261 last week; of this number 68 were registered in London, 16 in Manchester, 12 in Liverpool, 10 in Birmingham, 9 in Stoke-on-Trent, and 8 in Sheffield. The deaths referred to whooping-cough, which had been 32, 27, and 45 in the three preceding weeks, were 46 last week, and included 11 in London, 5 in Liverpool, 4 in Manchester, and 3 in Birmingham. The fatal cases of diphtheria, which had been 49, 38, and 51 in the three preceding weeks, fell to 46 last week; 5 deaths occurred in London, 4 in Leeds, 3 in Birmingham, and 2 each in Edmonton, Grimsby, Bolton, and Rhondda. The deaths attributed to scarlet fever, which had been 16, 24, and 24 in the three preceding weeks, further rose to 34 last week, and included 6 in Salford, 3 in Warrington, 3 in Sheffield, and 2 each in Birmingham, Liverpool, and Manchester. The deaths referred to measles, which had been 25, 27, and 49 in the three preceding weeks, declined to 30 last week; 6 deaths were registered in Liverpool, 3 in London, 3 in Stoke-on-Trent, 3 in Sheffield, and 2 each in Norwich, Birmingham, and Stockport. The fatal cases of enteric fever, which had been 20, 13, and 18 in the three preceding weeks, were again 18 last week, and included 3 in London,

---

[1] THE LANCET, March 15th, 1913, p. 770.

3 in Wigan, and 2 each in Portsmouth, Bristol, and Rhondda. The number of scarlet fever patients under treatment in the Metropolitan Asylums and the London Fever Hospital, which had steadily risen from 2112 to 3580 in the nine preceding weeks, had further increased to 3731 on Saturday last; 619 new cases were admitted during the week, against 575, 530, and 534 in the three preceding weeks. These hospitals also contained on Saturday last 1192 cases of diphtheria, 167 of whooping-cough, 80 of enteric fever, and 60 of measles, but not one of small-pox. The 1126 deaths from all causes in London were 104 fewer than the number in the previous week, and were equal to an annual death-rate of 13·0 per 1000. The deaths referred to diseases of the respiratory system, which had been 151, 178, and 207 in the three preceding weeks, slightly declined to 205 last week, and were 21 below the number recorded in the corresponding week of last year.

Of the 4561 deaths from all causes in the 96 towns, 176 were attributed to different forms of violence and 353 were the subject of coroners' inquests. The causes of 28, or 0 6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Sheffield, Leeds, Bristol, Bradford, Hull, and in 55 other smaller towns. Of the 28 uncertified causes of death, 7 were recorded in Birmingham, 2 in Grimsby, and 2 in Rhondda.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns, with an aggregate population estimated at 2,259,600 persons at the middle of this year, 1034 births and 608 deaths were registered during the week ended Saturday, Nov. 8th. The annual rate of mortality in these towns, which had been 13 9, 14·0, and 14·7 per 1000 in the three preceding weeks, declined to 14·0 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 14·3, against 13 6 per 1000 in the 96 large English towns. Among the several Scotch towns the death-rate last week ranged from 5·4 in Hamilton, 6·0 in Kilmarnock, and 6·1 in Clydebank, to 15·3 in Edinburgh, 15·6 in Coatbridge, and 17·9 in Dundee

The 608 deaths from all causes were 27 fewer than the number in the previous week, and included 55 which were referred to the principal epidemic diseases, against 62 and 82 in the two preceding weeks. Of these 55 deaths, 19 resulted from infantile diarrhœal diseases, 11 from measles, 11 from diphtheria, 10 from scarlet fever, and 4 from whooping-cough, but not one from enteric fever or from small-pox. These 55 deaths from the principal epidemic diseases were equal to an annual death-rate of 1·3 per 1000, which coincided with the rate in the 96 large English towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had been 29, 19, and 34 in the three preceding weeks, declined to 19 last week; of this number 11 were registered in Glasgow and 4 in Edinburgh. The deaths referred to measles, which had been 14, 12, and 17 in the three preceding weeks, fell to 11 last week, of which 5 were recorded in Glasgow and 2 in Edinburgh. The fatal cases of diphtheria, which had been 8, 11, and 11 in the three preceding weeks, were again 11 last week, and comprised 5 in Glasgow, 3 in Aberdeen, 2 in Greenock, and 1 in Dundee. The deaths attributed to scarlet fever, which had been 13, 11, and 14 in the three preceding weeks, declined to 10 last week, of which 4 occurred in Glasgow. The 4 deaths referred to whooping-cough were slightly below the average in the earlier weeks of the quarter.

The deaths referred to diseases of the respiratory system, which had been 80, 92, and 99 in the three preceding weeks, declined to 84 in the week under notice; 29 deaths were attributed to different forms of violence, against 18 and 32 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,199,180 persons at the middle of this year, 595 births and 404 deaths were registered during the week ended Saturday, Nov. 8th. The annual rate of mortality in these towns, which had been 16·0, 17·8, and 17·2 per 1000 in the three preceding weeks, rose to 17·6 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 17·3 per 1000; in the 96 large English towns the corresponding rate did not exceed 13·6, while in the 16 Scotch towns it was equal to 14·3 per 1000. The annual death-rate last week was equal to 19·4 in Dublin (against 13·0 in London and 14·6 in Glasgow), 17·5 in Belfast, 18·4 in Cork, 21·6 in Londonderry, 21·7 in Limerick, and 20·9 in Waterford, while in the 21 remaining smaller towns the mean death-rate did not exceed 12 0 per 1000.

The 404 deaths from all causes were 9 in excess of the number in the previous week, and included 34 which were referred to the principal epidemic diseases, against numbers steadily declining from 132 to 41 in the eight preceding weeks. Of these 34 deaths, 16 resulted from infantile diarrhœal diseases, 8 from scarlet fever, 5 from whooping-cough, 3 from measles, 1 from enteric fever, and 1 from diphtheria, but not one from small-pox. The mean annual death-rate from these diseases last week was equal to 1·5 per 1000, against 1·3 in the 96 large English towns and in the 16 Scotch towns. The deaths of infants (under 2 years of age) attributed to diarrhœa and enteritis, which had steadily decreased from 111 to 27 in the eight preceding weeks, further declined to 16 last week, and included 7 in Dublin, 3 in Belfast, and 2 in Kilkenny. The deaths referred to scarlet fever, which had been 4, 9, and 5 in the three preceding weeks, rose to 8 last week, and comprised 7 in Belfast and 1 in Dublin. Of the 5 fatal cases of whooping-cough, which were slightly in excess of the average in the earlier weeks of the quarter, 3 occurred in Galway. The 3 deaths attributed to measles were equal to the average in the three preceding weeks, and comprised 2 in Dublin and 1 in Londonderry. The death from enteric fever occurred in Belfast, and that from diphtheria in Dublin.

The deaths referred to diseases of the respiratory organs, which had been 48, 53, and 61 in the three preceding weeks, further rose to 69 in the week under notice. Of the 404 deaths from all causes, 127, or 31 per cent., occurred in public institutions, and 9 resulted from various forms of violence. The causes of 13, or 3 2 per cent., of the total deaths, were not certified either by a registered medical practitioner or by a coroner after inquest; in the 96 large English towns the proportion of uncertified causes of death did not exceed 0·6 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: E. G. E. O'Leary to the *Invincible*; and H. Spicer to the *Indefatigable*. Surgeons: S. Punch to the *Indefatigable*; and E. Moxon-Browne to the *Tamar*, additional, for Hong-Kong Hospital, and to the *Triumph*, additional, for

Henry, George Foster Braithwaite Page, Alexander John Patterson, William Agar Scholefield Duck, Frederick Cecil Wright, Bernard Edward Patrick Sayers, David Greig Arthur, Alexander Simpson, Henry Ellis Yeo White, Michael Meehan, Devonshire Penrose Hawkes Pearson, Ivor Stanley Gabe, and Arthur John Tozer (dated April 11th, 1913).

ROYAL ARMY MEDICAL CORPS.

Major Edmund P. Hewitt is placed temporarily on the half-pay list on account of ill-health (dated Nov. 7th, 1913).

Colonel J. Maher has relinquished charge of the Queen Alexandra Military Hospital and taken up duty in the Gibraltar Command as Assistant Director of Medical Services.

Lieutenant-Colonel J. J. Gerrard, senior medical officer in the Sierra Leone Protectorate, has arrived home for duty from West Africa. Lieutenant-Colonel H. N. Thompson, D.S O., has been appointed to the Scottish Command. Lieutenant-Colonel C. C. Reilly has been appointed to hold charge of the Military Hospital at Colaba, Bombay. Lieutenant-Colonel J. W. Bullen has been appointed to the Northern Command for duty. Lieutenant-Colonel H. D. Rowan has been appointed to hold charge of the King George V. Military

Hospital at Arbor Hill, Dublin. Lieutenant-Colonel M. O'D. Braddell has been appointed to the Irish Command for a tour of duty. Lieutenant-Colonel G. S. McLoughlin, D.S.O., has been appointed to hold charge of the Military Hospital at Winchester.

Major A. D. Waring has taken up duty at the Military Hospital, Hilsea. Major W. Tibbits has embarked for a tour of service in India. Major A. W. A. Irwin has joined at Cork. Major J. C. B. Statham has arrived home for duty from the Sierra Leone Protectorate. Major D. J. Collins has been transferred from the Military Hospital at Poona Cantonment to Kirkee. Major G. B. Crisp has arrived in Hong-Kong for a tour of service. Major H. W. Long has taken up duty at the Military Hospital, Devonport. Major B. B. Burke has been appointed to the Military Hospital at Dover. Major H. L. W. Norrington has arrived home on leave of absence from the Military Hospital at Malta. Major E. A. Bourke has been appointed for duty at the Military Hospital, Pembroke Dock. Major N. J. C. Rutherford has been selected for appointment as Specialist Sanitary Officer to the Cork District. Major C. W. Reilly has been appointed to hold medical charge at Bodmin.

Captain J. T. McEntire has arrived home on leave of absence from the Sierra Leone Protectorate. Captain N. E. J. Harding has been appointed to the London District for a tour of duty. Captain L. A. A. Andrews has been transferred to the Northern Command from the Military Hospital at Cork. Captain W. G. Maydon has been selected for appointment as Adjutant to the Royal Army Medical Corps School of Instruction in the West Lancashire Division. An exchange on the roster for service abroad has been approved between Captain C. P. O'Brien-Butler and Captain H. L. Howell. Captain W. F. H. Vaughan has embarked for a tour of service in Malta. Captain C. M. Drew has arrived home on leave of absence from Cairo. Captain B. A. Odlum has been selected for appointment as Instructor in Medical Corps duties at the South African Medical College. Captain J. G. Bell has embarked for a tour of service in the Straits Settlements. Captain H. J. Crossley has been appointed to the Military Hospital at Meerut Cantonment. Captain W. R. O'Farrell has arrived home on leave of absence from the Military Hospital at Alexandria. Captain P. J. Hanafin has been transferred to the Military Hospital at Dublin from Rogerstown Camp. Captain H. M. J. Perry has been selected for appointment as Specialist in Bacteriology and Prevention of Disease at Devonport. Captain A. W. Bevis has joined at Belfast. Captain W. E. Marshall has arrived home on general leave of absence from the Military Hospital at Cairo. Captain T. S. Dudding has been placed under orders for a tour of duty in India. Captain H. W. Russell has embarked for a tour of service in India. Captain A. C. Osburn has taken up duty at the Royal Victoria Hospital, Netley. Captain C. T. Edmunds has been transferred from Fawley Court to Bulford Camp. Captain W. Mathieson has arrived home on general leave of absence from the Military Hospital at Pretoria. Captain F. C. Sampson has been selected for appointment as Specialist in Dermatology and Venereal Diseases. Captain M. J. Lochrin, Captain E. M. Middleton, and Captain A. W. Howlett have been placed on duty on board the transport ss. *Plassy*, which left Bombay for Southampton on Nov. 7th with time-expired troops. Captain A. S. Arthur has been appointed to the Military Hospital at Liverpool. Captain T. W. Stallybrass has arrived home on general leave of absence from the Military Hospital at Khartoum. Captain R. C. Hallowes has been appointed to the Military Hospital at Omagh. Captain W. J. E. Bell has joined the London District for a tour of duty. Captain E. C. Lang has been transferred from Maryborough Heath Camp to the Military Hospital at the Curragh. Captain T. C. C. Leslie has taken up duty at the Military Hospital, Cork. Captain R. E. Porter has been transferred from Poeghane Camp to the Military Hospital at Nenagh. Captain F. A. H. Clark has been appointed to hold charge of the Brigade Laboratory at Calcutta. Captain A. D. Fraser has been appointed to the Royal Victoria Hospital at Netley, on transfer from London. Captain P. M. J. Power has been appointed to the Military Hospital at Cosham. Captain A. M. Pollard has been appointed for duty to the Military Hospital at Colchester. Captain C. A. T. Cunningham has been appointed Specialist in Dermatology and Venereal Diseases to the Fifth (Mhow) Division of the Southern Army in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel G. G. Giffard has taken up duty as Superintendent of the Government Maternity Hospital, Madras Presidency. Lieutenant-Colonel A. E. Berry has been granted general leave of absence home from India for one year. Lieutenant-Colonel H. E. Banatvala has been appointed to officiate as Inspector-General of Civil Hospitals and Prisons and Sanitary Commissioner in Assam, vice Colonel R. N. Campbell, C.B., C.I.E., who has arrived home on leave.

Major H. B. Foster has been appointed to officiate as Professor of Medical Jurisprudence at the Goverment Medical College, Calcutta, during the absence on leave of Major O. St. John Moses. Major A. E. J. Lister has been appointed Professor of Physiology on the staff of King George's Medical College at Lucknow. Major A. M. Jukes has been confirmed in his appointment as Deputy Sanitary Commissioner to the Burdwan and Presidency circles in Bengal. Major J. W. Grant has been granted privilege leave of absence by the Government of India. Major H. A. J. Gidney, civil surgeon at Naga, has been deputed to Delhi by the Assam Administration in connexion with the prevention of malarial fevers.

Captain A. J. V. Betts has been granted leave of absence on medical certificate. Captain F. P. Mackie has been appointed to the Bacteriological Department of the Government of India. Captain H. C. Keates has been granted leave of absence. The services of Captain M. J. Quirke have been placed permanently at the disposal of the Government of Madras for employment in the Sanitary Department. Captain R. E. Flowerdew has been appointed to hold substantive medical charge of the 99th Regiment of Deccan Infantry. Captain J. S. Fitzgerald has been selected for appointment in the Bombay Jail Service. The services of Captain W. S. McGillivray have been placed temporarily at the disposal of the Burmese Administration for employment on plague prevention duty. Captain N. M. Wilson has been granted leave of absence. The services of Captain S. J. Bathena have been replaced at the disposal of the Commander-in-Chief. Captain A. C. Ingram has taken up duty in Madras Presidency.

Lieutenant P. F. Gow has been selected for appointment as Specialist in the Prevention of Disease and placed in charge of the Bacteriological Research Laboratory at Brigade Headquarters, Allahabad. Lieutenant P. J. Veale has been granted eight months' general leave of absence home from India on medical certificate.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Lieutenant Thomas Lindsay to be Captain (dated Nov. 12th, 1913). Lieutenant George Rollason resigns his commission (dated Nov. 12th, 1913). Lieutenant Frederick L. Tulloch is confirmed in his rank.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Colonel William Coates, C.B., Territorial Force Reserve, is appointed to the Honorary Colonelcy of the Royal Army Medical Corps in the East Lancashire Territorial Division (dated Nov. 12th, 1913).

Colonel Joseph Whitfield Blandford, Retired List (late of the Army Medical Service), is appointed to the Honorary Colonelcy of the Royal Army Medical Corps in the Northumbrian Territorial Division, vice Honorary Colonel Sir George H. Philipson, Knight, who vacates the appointment (dated Nov. 11th, 1913).

6th London Field Ambulance, Royal Army Medical Corps: Lieutenant Frank Colman, from the 5th London Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Oct. 13th, 1913).

3rd Lowland Field Ambulance, Royal Army Medical Corps: Captain James H. H. Pirie is seconded under the conditions of paragraph 112 of the Territorial Force Regulations, for service under the Colonial Office (dated Oct. 1st, 1913).

2nd London (City of London) General Hospital, Royal Army Medical Corps: Captain Henry P. Dean resigns his commission (dated Nov. 12th, 1913).

1st Western General Hospital, Royal Army Medical Corps: Lieutenant-Colonel Thomas H. Glynn resigns his commission (dated Nov. 12th, 1913). Major Sir Ronald Ross, K.C.B., to be Lieutenant-Colonel (dated Nov. 12th, 1913). Captain Peter Davidson to be Major (dated Nov. 12th, 1913). Captain

Arthur John Evans, from the 1st West Lancashire Field Ambulance, Royal Army Medical Corps, to be Captain, whose services will be available on mobilisation (dated Nov. 12th, 1913).

Attached to Units other than Medical Units.—Lieutenant James M. Kirkness to be Captain (dated August 1st, 1913). The undermentioned Lieutenants resign their commissions (dated Nov. 12th, 1913): Richard C. Roberts and Frederick G. Harper.

THE ROYAL AUTOMOBILE CLUB AS A HOSPITAL IN TIME OF WAR

At a recent meeting of the committee of the Royal Automobile Club the following resolutions were adopted :—

[illegible]

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

In the November issue of the *Journal of the Royal Army Medical Corps* Colonel W. H. Horrocks returns to the subject of the variation of the bacillus typhosus. His present conclusions are that under certain conditions B. typhosus may be converted into B. fæcalis alkaligenes, but he is unable to afford any evidence as to the epidemiological significance of this variation. "The B. fæcalis alkaligenes appears to have no pathogenic effect on ordinary laboratory animals, and it has not been possible to reconvert this variant into the B. typhosus." The military great coat, which, by the way, we do not hear of being used in the British army until the reign of Elizabeth, is the subject of a very interesting article by Captain N. Dunbar Walker, who discusses the construction and use of this garment by the armies of Europe, of America, and of Japan. Dairies and Cowsheds, their Effect upon the Purity of the Milk Supplied to Military Hospitals, Troops, and Married Families, by Staff Sergeant E. B. Dewberry, R.A.M.C.; Kala-Azar in an Adult from Malta, by Fleet-Surgeon P. W. Bassett-Smith; a case of Death from Syphilis occurring Nine Days after Injection of Salvarsan, by Captain J. H. Duguid and Lieutenant W. T. Graham; and the Phylactic Use of Quinine, by Lieutenant-Colonel H. N. Thompson, are other matters dealt with in the present issue of the *Journal.* Students of military history will appreciate the excerpts from old records by Colonel R. H. Firth on Some Indian General Orders.

NAVAL MEDICAL CONSULTATIVE BOARD.

Surgeon-General John J. Dennis has been appointed a naval member of the Naval Medical Consultative Board in the place of Surgeon-General Howard Todd, C.B., K.H.S., retired. Sir John Tweedy has been appointed a civilian member of the Board.

MIDDLESEX COUNTY COUNCIL AND THE TREATMENT OF TUBERCULOSIS.—[illegible] of the Middlesex county [illegible] tions had been received fr[illegible] from tuberculosis for institutional treatment. Hitherto sanatorium treatment had been limited to insured persons, [illegible] progress [illegible] he treat-[illegible] persons contributed towards the cost of sanatorium benefit it would only be equitable that a contribution towards the cost should be made by non-insured patients, the amount being considered in each case on the merits. The council passed the following resolutions :—

> That where the council think it advisable the treatment of non-[illegible] from tuberculosis be undertaken at hospitals, [illegible] the county council upon the basis of [illegible] possible, by the patient towards the [illegible]
>
> That institutional treatment be undertaken only so far as accommodation is available at any of the hospitals or sanatoriums under the control of the county council, or to which it has agreed to send patients.
>
> That the public health committee be *authorised to sanction the above* treatment and to settle the amount of the contribution, if any, in each individual case.

MOTORING NOTES.

(FROM A SPECIAL CORRESPONDENT.)

A Stand-to-Stand Visit of Inspection at the Olympia Exhibition.

WITH over 300 exhibits, the doctor in search of a car will feel confused unless he relies rigidly upon one factor in his choice—namely, the price which he will give. Generally speaking, there are two classes of doctors who need motors. There is the town and country specialist, to whom price is of little importance, and who will find in either a Rolls-Royce, a Delaunay-Belleville, an Armstrong-Whitworth, a Wolseley, a Lanchester, a Renault, a Sunbeam, a Vauxhall, a Fiat, a Minerva, a Napier, or a Clement-Talbot a car that will fulfil all his wants. Any of these are sure to give satisfaction, the price varying from about £1200 or £1300 for a Rolls-Royce to about half, or less than half, of that amount for some of the cheaper makes. The other class is the general and country practitioner, and the question of expense with the major part of them has to be considered. This class can probably be again divided into two — those who merely want a two-seater for their professional work, and those who would like a car which they could also use for week-end or other holidays with their families. If it is a matter of expense, it should be borne in mind that the light two-seater is much cheaper, not only to buy, but also in running cost and upkeep.

Messrs. Alldays and Onions show their two- and four-cylinder models. *Their new four-cylinder 10 h.p is a model* of sound engineering, and one worthy of the doctor's consideration. The brake adjustment is by means of thumbscrews in very accessible positions, and the body provides plenty of room for the occupants. The 10 h.p. Midget has a two-cylinder engine, and makes an excellent light two-seater.

Messrs. Argylls, Limited, show on Stand No. 73 their 12–18 h.p. poppet valve and samples of their later models of sleeve Argyll engines Their coachwork as well as their chassis is bound to attract great attention.

The Ariel and General Repairs, Limited, show the Hurtu 10 and 14 h p. cars, both with four cylinders Little alteration has been made to their last year's model, except that now the gearbox gives four forward speeds, and provision has been *made at the foot of the engine for fixing a dynamo* for lighting purposes.

Messrs. Bayard show a two-seater torpedo fitted with a four-cylinder 60 mm. × 120 mm. engine. The polished mahogany covering for the petrol tank and *one-man type* hood make the model very attractive.

Messrs. F S. Bennett, Limited, show on Stand No 108 the new Cadillac motor This is certainly replete with novelties; these include two direct drives by means of two pairs of bevel gears, either for working alternatively or giving the car two different gear ratios. An electric starter is also fitted, and the gears are changed by means of an electric control.

Briton Motors Company, Limited, show their two seater, fully equipped with a 68 mm. × 120 mm. four-cylinder engine, which has been previously described in these Notes, and should certainly be inspected by the doctor in search of a car at less than £200. The price is 175 guineas for a two-seater and £200 with a four-seated streamline body.

The exhibit of the Darracq Company has always been of interest. *This year the great* attraction is their 12 h.p and 16 h.p. car, designed by Mr. Owen Clegg. Both are full of new features. The chassis cannot claim all the improvements, for the coachwork fitted shows a very marked advance both in design and *workmanship*, and it is pleasing to note that this also is produced in the Darracq factory at Fulham. The 12 h.p. is shown as a torpedo and limousine landaulette. There will be a large sale of this high-class model.

The models of the *De Dion Bouton Company* are to be seen on Stand No. 74, the most noticeable feature being the introduction of a small four-cylinder model in place of the twin-cylindered model used for so many years past. This new 8-10 h.p. chassis has a four-cylindered 56-120 mm. monobloc engine, and is supplied as either a two-, three-, or four-seated car. It has a chain-driven single camshaft, chain drive to magneto and oil pump, and thermo-syphon cooling, assisted by a fan mounted on an adjustable bracket. The valves are enclosed, the carburetter is the De Dion-Zenith, and the magneto is a Bosch. The price for chassis, tyres, and tool kit is £221. Other models are also shown.

The Hillman Motor Company show four types of their new 9 h.p. car, fitted either as a two-seater with hood, &c., or as a two-seater coupé, which would make a very useful car for professional use.

Messrs. Metallurgique, Limited, are on Stand 99. Their 15-20 h.p. is an improved edition of their 1913 type. A special platform is arranged for an electric light dynamo, and, as is now so universal, the valve gear is driven by a silent chain.

Messrs. Morgan and Co. exhibit on Stand No. 80 three entirely new Adler models. There is a 9 h.p. with a four-cylinder monobloc engine 65 × 98 mm., complete with Morgan two-seated body, also a chassis of the same type. They also manufacture a tandem two-seater on this chassis, and it is essentially one that should be considered by all in search of a light two-seater. The 11-16 h.p. chassis has a four-cylinder engine 67 × 110 mm., cast in pairs, fitted with the latest design Morgan coupé-landaulette body, and the 20-30 h.p. chassis has a four-cylinder engine 86 × 135 mm., equipped with the "Morgan" new patent cabrio-landaulette body. The popular 14-18 h.p. model, fitted with the latest design "Morgan" torpedo body, is also shown.

Messrs. W. R. Motors, Limited, show the Morris-Oxford Light Car, which has a White and Poppe engine and carburetter, and all the brakes are on the back axle. Three-quarter elliptic springs are fitted, so the riding should be most comfortable. The price for a two-seater model de luxe is 190 guineas, complete with Sankey detachable wheels, but the ordinary type is listed at £180. This little two-seater is especially worth close inspection.

The cars of the Rover Company, Limited, have always appealed to doctors, and their exhibit of their 12 h.p. models, with different type bodies, should certainly attract attention. There is little alteration in their 1914 cars, except that the wheel-base has been increased and a dynamo lighting outfit is supplied as a standard equipment.

The Sunbeam Company show on Stand 101 some very good examples of their 12-16 and 16-20 chassis. There are no changes to record in the main design of this car, last year's models having given such universal satisfaction.

The Swift Company, on Stand 42, show samples of their 11·9 and 15·9 cars. The former as a two-seater is sold at £285, and the latter with a streamline body, including a dynamo electric lighting set, is £385. Both of these cars are certainly worthy of close attention by those who can run to these prices.

Clement Talbot, Limited, show four cars. Their 12 h.p., which sells at £410 complete, is the one most likely to appeal to doctors.

The Vulcan Motor and Engineering Co., Limited, have made practically no changes in their 10 h.p. engine, but their 15 h p. model has a new monobloc engine. A good many doctors have had these cars and have reported most favourably concerning them.

The stands of the Belsize Company and of the Star Engineering Company should be visited, as both make cars eminently suitable for medical men.

Tyre exhibits are always interesting, and the points which seem to have advanced are the greater use of bolt-plate valves and detachable rims and wheels.

The Warland detachable rim, which is used on a good many cars, including the De Dion, certainly seems a favourite, and is to be recommended. All the tyre manufacturers are well represented in the gallery—the Dunlop, the Continental, the Michelin, the Palmer, the Stepney Spare Motor Wheel, Limited, and the Wood-Milne, Limited. The two latter have exceedingly satisfactory all-rubber non-skids, and the manufacturers named produce goods that can certainly be relied upon.

From tyres it is but a step to tyre-repairing appliances, and those of Messrs. Harvey Frost and Co., Limited, create genuine interest on account of the new models and the important additions to existing models.

Messrs. H. M. Hobson, Limited, show a full range of sparking plugs. This year they have brought forward a new type of plug, which is shown at Olympia for the first time, and will be on sale on and after December 1st. The special purpose of this plug is to do away with the wear of the electrodes due to the action of the voltaic arc when the engine is running. This voltaic arc volatilises the molecules of the electrodes, and in consequence the distance between the sparking points widens, and renders easy starting, or starting at all, impossible. Similarly, the electrode may melt and the spark lose its energy, or surplus oil sticking on the electrodes may cause other troubles. The new arrangement of the patent expanding electrode does away with these troubles. The insulated centre stalk is made in its whole length of two metals, riveted and soldered together, but with different co-efficients of expansion. Owing to its varying expansion this centre stalk bends more and more as the heat increases, hence it can be easily understood that this electrode, when brought nearer to the electrode attached to the body of the plug, facilitates the starting of the engine, as the spark jumps across easily. Then, as the speed of the engine increases, the patent electrode gets hotter and hotter, and consequently bends farther away from the electrode on the body of the plug, and this wider gap causes the spark to give out its maximum heat and power at all speeds of the engine.

Messrs. Brown Bros., Limited, have an interesting range of motor accessories, such as the Brolt electric lighting installation, the autoclipse lamps made for either acetylene or electricity, the popular Gabriel horn, the shock absorber which was described previously in these Notes, as well as the Sampson plug for repairing punctures, which was also recently fully described. A great many owners like to do a good bit of repairing work themselves, and for those who care to remove the carbon deposit from their cylinders, instead of having it burnt out, the "Success" carbon-removing tools will appeal. They enable the cylinder head and piston to be thoroughly scraped as well as the edges of the parts. After the carbon has been scraped the deposit can be blown into the valve chambers by a tyre pump, whence it can be spooned up by means of the special tools provided.

Speedometers are accessories which, though not necessary, are certainly very much in favour. Messrs. Stewart have always produced a reasonable and popular one, and their 1914 models have certainly an advantage over the older ones, as provision is made for lubrication of the wheel-driven bevels, which in the older days occasionally gave trouble through wear. Messrs. S. Smith and Son and Messrs. Markt and Co. also show excellent speedometers, which are sure to give satisfaction.

Some who have to travel in all weathers may be attracted by the Thompson-Bennett exhaust car heater. This firm also show the warning-tone horn, which is merely worked by a small hand plunger, without the use either of a mechanical driver or of electricity.

Electric car lighting has now become almost a necessity, especially for doctors. Of course, accumulators can be used and will supply sufficient current for ordinary side and head lights, but they have to be kept charged, and occasionally they may get run down and cause anxiety as to whether the light will last for the return home journey. This, of course, should not occur if they are kept charged, but all this worry can be avoided by an electric light installation driven off the engine.

The Imperial Motor Industries, the Motor Accessories Company, Messrs. S. Smith and Sons, the Rotax Motors Accessories Company, Messrs. Peto and Radford, the Mira Magnetolite, and Messrs. C. A. Vandervell and Co. all show exceedingly neat dynamos and fittings for car lighting. That shown on the stand of the Imperial Motor Industries is of exceptional interest, as it also combines a self-starter. The question whether a high voltage or low voltage is preferable is greatly a matter of taste. The writer rather inclines to a low voltage, and one point which he thinks should be insisted upon is that the dynamo can easily be disconnected when not required for accumulator charging or lighting.

The Atlas Inner Case Syndicate show a useful petrol filler, which is also a strainer, as well as their impulse pump, which latter is certainly of value, and was fully described some time ago in these Notes.

The Scott's Starter Syndicate, Limited, also show an efficient electric starter and lighting generator.

The general impression of the exhibition is that it is very much like its predecessors, except that there are more exhibits. Leather-faced cone clutches are as popular as ever, for which I think the doctor should be grateful, as they are satisfactory, and even if the leather does wear it can easily be replaced. Four-speed gear boxes are ousting the three-speed, and smaller engines are more universal. The exhibition is certainly like a good pudding—it has plenty of plums in it, and there is now much more likelihood of a purchaser drawing a plum than there was in the past.

Any of the cars mentioned above can, in the writer's opinion, be safely bought by doctors with almost a certainty of good and efficient service, provided the purchaser, either personally or by his chauffeur, takes care of his car.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Cremation in Manchester.

FROM the annual report of the Manchester crematorium we learn that the cremations last year reached 159, the numbers for the four previous years being 117, 110, 113, and 147. The number of visitors paying for admission to see the crematorium (1667) also showed an increase. The numbers present at cremation funerals reached 5330. The directors state that attendance at cremation funerals is largely effective in removing prejudice against cremation. There are 13 crematoria in the kingdom, and only one, that at Golder's Green, had more cremations last year than the Manchester crematorium. After defraying all expenses there is a surplus of £418, while the accumulated surplus amounts to £634, and the reserve account stands at £800.

Burnley Victoria Hospital.

Mr. Edward Green has intimated to the Burnley Victoria Hospital authorities that his wife and her sister, Mrs. Greenhalgh, will contribute £1000 for a cot to be placed in their names in the female ward.

The Birth-rate in Manchester.

Dr. E. Sergeant, the county medical officer, in his recent report stated that the birth-rate for Lancashire in 1912 was the lowest on record, with the exception of 1910. In Manchester up to the end of September there has been an appreciable increase in the birth-rate.

Nov. 11th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Dinner of the Medical Institution.

THE biennial dinner was held on Nov. 8th at the Exchange Station Hotel, when about 160 members and guests sat down. Among the guests were the Bishop of Liverpool, the Lord Mayor, Dr. W. S. A. Griffith, and the Presidents of the medical societies of Chester, Birkenhead, St. Helen's, and Wallasey. Mr. Robert Jones, the President of the society, was in the chair. After the usual loyal toasts, Dr. Caton proposed "The City and Port of Liverpool," and spoke of the many improvements that were taking place. The Lord Mayor, in replying, paid a high tribute to the work of the profession, and more especially to the work of the Tropical School, inasmuch as the world owed the completion of the Panama Canal to tropical research. He thought the greatest requirement now was better means of communication between the two banks of the river, so as to unite the population of the district. The Bishop of Liverpool proposed "The Liverpool Medical Institution," and gave a short account of its origin in the eighteenth century and how it had grown by the union of three parent societies between 1830 and 1840. He said it was owing to the Medical Institution that the idea of a Liverpool University had begun. The President, in replying, said that the institution could boast of as great activity and as large meetings as any society in the country. Dr. Griffith, in replying for the guests, said that Dr. Rutter, in founding the society in its present form, had hoped that it might and would be the means of uniting its members in a firm and compact body, working on individualistic lines but in friendliness and with mutual esteem. A society such as this, by bringing its members constantly into contact with one another, might fulfil the wishes of its founder.

Visit of Sir Dyce Duckworth.

Sir Dyce Duckworth has been visiting the city of his birth as the guest of Mr. T. H. Bickerton, who entertained a large party at dinner to meet him before the meeting at the Medical Institution. After the meeting there was an informal gathering at Mr. Bickerton's house, when about a hundred medical men had the pleasure of hearing from Sir Dyce Duckworth his reminiscences of bygone Liverpool medical men. Among a large number of past leaders Sir Dyce Duckworth paid especial tribute to the Bickersteths, quoting Symes as having said that E. R. Bickersteth was "the finest surgeon in England."

The Passing of Two Notabilities.

Two well-known figures for many years connected with the Royal Infirmary have passed away—the Rev. William Smith and Mr. James Lister. Mr. Smith was chaplain at the infirmary from 1865 until he resigned about a year ago. He died quite suddenly on his way to church on Sunday, Oct. 26th. Mr. Smith had qualified as a medical man. Under rather an austere exterior there was a kindly personality which endeared him to those who really knew him. Mr. James Lister had for many years been a member of the committee of the Royal Infirmary, in which he took the greatest possible interest, making frequent visits there and personally knowing many residents, nurses, and patients.

Nov. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in Lanarkshire.

ARRANGEMENTS are now in progress for a joint sanatorium for the burghs of Hamilton, Motherwell, Wishaw, and Rutherglen, and a site has been purchased on the estate of Muirbank, Strathaven. It is proposed to build a hospital pavilion for 20 beds, [illegible] each with 20 beds, and two [illegible] same capacity; an adminis- [illegible] will be replaced for a further two minutes, after which four of them read 98·0° and one 97·6°. The clear duty of every conscientious practitioner is obvious—namely, to test every clinical thermometer he buys, in regard both to the accuracy of its graduation and to the time taken in reaching the temperature of the surrounding medium.

I am, Sir, yours faithfully,
Nov. 8th, 1913. PHYSICIAN.

, These observations agree with the conclusions published in our issue last week. We then wrote: "For really accurate observations the 30 seconds thermometers give, generally speaking, more satisfactory results when they are incubated for more than 30 seconds, and according to the above experiments an incubation of a period of two minutes records the practical truth."—ED. L.

THE MEDICO-PSYCHOLOGICAL CLINIC.

To the Editor of THE LANCET.

SIR,—It has been impossible to ignore the press notices of the inaugural meeting of the Medico-Psychological Clinic. It is distressing to the committee to find that a great deal of misunderstanding has arisen, and we feel bound in justice to ourselves, to the pioneers of psychotherapy, and to the supporters of our movement to dissociate ourselves entirely and absolutely from the occult powers that Lord Sandwich claimed for himself. Lord Sandwich has expressed his sincere regret to the committee for the misunderstanding he has caused, and this terminates his association with the clinic and with the committee.

We profess nothing but ordinary medical knowledge acquired in the ordinary way. We have no gifts or methods not open to every practitioner. It is our belief that the clinic will attract cases of threatened nervous breakdown in a stage at which preventive measures may avert calamity. It will offer a place of study for medical practitioners who wish to acquaint themselves with practical psychotherapy. The whole of the healing art was cradled in superstition. In the minds of many psychotherapy is still tinged with charlatanism, and from this the clinic will help to dissociate it.

We feel sure that the profession will appreciate to the full the difficulties and delicacy of the work we have in hand, the dangers to be avoided and prejudices to be overcome, and we trust that it will join with us in aiding a work which must of necessity be the object of adverse criticism and unavoidable misconceptions in its early stages.

We are, Sir, yours faithfully,
HECTOR MUNRO.
J. M. MURRAY.
JOHN SPENCER.

Endsleigh-street, W.C., Nov. 10th, 1913.

THE NATIONAL INSURANCE ACT.

To the Editor of THE LANCET.

SIR,—The figures below are of some interest if they are like those of others practising amongst the insured. The figures will doubtless expand during the winter months, and I reckon the payment we receive will work out at barely 1s. per professional attendance—an inadequate sum. Total acceptances, April 15th, 1078; June 30th, 1136; average per quarter, 1107. For 1107 persons accepted for treatment there were, visits, 187; attendances, 1261. June 30th to Sept 30th: Average acceptances, 1146; visits, 136; attendances, 1164. Total number of persons who have seen me once or oftener since April 15th, 601, or 50 per cent. of total on my list.

I am, Sir, yours faithfully,
Brighton, Nov. 8th, 1913. CHAS. FRASER.

THE NATIONAL INSURANCE ACT AND MEDICAL REFEREES.

To the Editor of THE LANCET.

SIR,—At the recent meeting of the London Insurance Committee, of which a short report appeared in THE LANCET of Nov. 1st, a recommendation of the General Purposes Subcommittee was considered which seems to me to raise questions of much importance.

The proposal was that the services of medical referees should be made available to Approved Societies desiring advice (1) as to whether an insured person was incapacitated as a result of illness or injury which might entitle him to receive or recover any compensation or wages under the Workmen's Compensation Act, 1906, or under the Employers' Liability Act, 1880, or otherwise as provided in Section 11 of the National Insurance Act, or (2) as to whether the insured person was suffering from a disease caused by misconduct in respect of which sickness benefit may be suspended under the provisions of Section 14 (2) of the Act. It was further recommended that the expenditure involved could be met out of the sum of £1000 authorised for the services of medical referees out of the Benefits Administration Fund.

The recommendation, I observe, met with opposition upon the committee, Mrs. Handel Booth moving that it should be referred back, but was accepted by a majority. It certainly appears to tend to impose upon medical referees duties outside those for the performance of which their appointment has appeared necessary and has been generally approved. Moreover, it seems to me that it would bring them into unnecessary contact with the Approved Societies and to constitute them investigators of matters outside the expression of medical opinion upon questions of disease. As I understand the matter, the contract for medical attendance is between the medical man and the Insurance Committee, and the certificate given by the medical man should state with accuracy the nature of the disease from which his patient suffers. It may be necessary or desirable that a medical referee should consider the accuracy of a statement as to the nature of a disease made in a certificate, and it may also be necessary or desirable that an Approved Society should be sure that its funds are not being depleted by a person who, owing to the manner in which his incapacity came about or his behaviour when under treatment, is not entitled to partake of them. It does not, however, follow that a medical referee should be employed to do more than make sure that a medical certificate correctly states medical facts, where *primâ facie* there is ground for suspicion that it does not do so. That the medical man attending a patient should have his attention called to the provisions of Section 11 or Section 14 (2) of the Act in respect of a particular case is not unreasonable. But his explanation or opinion on the question involved should be specifically obtained before a medical referee should be invited to intervene, and the intervention of the medical referee should be confined within strictly defined limits. I submit that these, where they involve inquiries into the original cause of incapacity and the behaviour of a patient, should not go beyond such inquiries as the medical attendant on the panel might reasonably make in the same direction.

I am, Sir, yours faithfully,

Nov. 6th, 1913. MEDICO-LEGAL.

THE NATIONAL INSURANCE ACT.

THE REVISED REGULATIONS FOR MEDICAL BENEFIT.

WE have received from the Insurance Commissioners a copy of the draft Regulations dated Nov. 7th, 1913, which they propose to make under Section 15 of the National Insurance Act, together with a leaflet (Memo. 185/I.C.) which deals with the method which has been adopted in revising the Regulations for medical benefit and with the arrangements for providing this benefit during the year 1914.

These Regulations, which will come into operation on Jan. 12th next, will shortly be on sale.[1] They take substantially the same form as the original Regulations for medical benefit which came into force last year. The Commissioners state that the revision embodied in these new Regulations was undertaken with a view to the adoption of numerous suggestions made as a result of actual working experience, and for the purpose of simplifying and facilitating administration for all parties concerned. This revision has been completed after consultation with the Advisory Committee.

The Commissioners in the accompanying memorandum draw attention to some of the more important amendments in the revised Regulations, and suggest means by which Insurance Committees may enter into agreement with medical practitioners and pharmacists on the basis of the revised terms of service. It is particularly noted that the new Regulations do not affect the amount available for the remuneration of panel practitioners in respect of their services under the Act. Owing to the great difficulties experienced in the allocation of insured persons and the calculation of payments due to practitioners the Regulations have been modified. Insurance Committees are now relieved of the obligation to attempt such an allocation, while the First Schedule has been amended so as to secure that the "quarterly credit" of each practitioner shall be calculated on the numbers on his list at the beginning of the quarter, thus enabling the preparation of the quarter's accounts to be undertaken soon after the commencement of the quarter.

The system of complete personal allocation having been abolished, an equivalent provision is made for distributing the available funds among practitioners on the panel, in accordance with the right which they respectively assume. By this device panel practitioners are to be credited with additional capitation fees equal in number to the number by which the insured population entitled to medical benefit at the beginning of the quarter exceeds the total number on the practitioners' lists at that date.

The Panel Committees (referred to in our last issue) are to make arrangements in advance for the assigning among doctors on the panel, or some of them, of insured persons who subsequently apply to be assigned; and the method of distribution of the additional capitation fees will take into consideration the responsibility thus placed upon individual practitioners for patients subsequently assigned to them during the quarter.

The memorandum explains the general effect of the changes made in the new Regulations under the heads of Removals and Temporary Residents. The Commissioners claim that the main effect of these changes is in the direction of greater simplicity and uniformity. With regard to complaints, the powers of Insurance Committees have been enlarged in some respects, while panel practitioners will be afforded a general right of appeal to the Commissioners against any decision of an Insurance Committee on a question investigated by the Medical Service Subcommittee. The revision of the First and Third Schedules has involved corresponding changes in some of the actual Forms of Agreement, while clauses have been drawn up so as to meet the widespread desire expressed by medical practitioners, and endorsed by the Advisory Committee, to obviate the need of an appeal to the law courts in case of dispute between a panel practitioner and an Insurance Committee, as well as to meet difficulties due to breaches of the practitioner's Agreement not sufficiently covered by the previous Regulations. The memorandum concludes with suggestions for expediting the arrangements made by Insurance Committees for providing medical benefit for the medical year commencing January 12th, 1914.

ABERDEEN INSURANCE COMMITTEE.

At a recent meeting of the Aberdeen Insurance Committee a minute of the finance committee was discussed to the effect that the Scottish Insurance Commissioners should be asked whether they would be prepared to sanction an expenditure of £100 annually upon putting into effect Section 60 (1) (b) of the Insurance Act, 1911, which says that an insurance committee "shall make such provision for the giving of lectures and the publication of information on questions relating to health as it thinks necessary or desirable.[1]" Mrs. Ogilvie Gordon and Dr. Forbes spoke in favour of taking action under the section, and dwelt upon the necessity for education in matters of health in order to preserve the well-being of the community; the chairman intimated that the Commissioners had expressed in a letter general sympathy in the proposal, and the meeting was unanimously in favour of steps being taken under the subsection referred to. The question of the choice of a medical attendant by the insured was also discussed. 7700 postcards had been issued to those who had not made their choice, and of these 2633 had been returned, the number of those who after being specially communicated with had selected medical men amounting to 3000. Mr. John Milne, who introduced the report dealing with this topic, said that it was "a matter that interested insured persons very deeply, but they had also recognised that the medical men had their rights in the matter." Apparently the question of distributing without further delay those insured persons who had not felt deeply enough interested to make their choice has not yet been dealt with at Aberdeen, and the report of what had taken place was adopted without it being raised. At the same meeting it was stated that the Commissioners, in reply to questions on the subject from the Medical Service Subcommittee, said that in terms of his agreement the insurance practitioner must, at the request of an insured person who was on his list, furnish free of charge such certificates of incapacity as were required to be furnished in connexion with any claim for sickness or disablement benefit made by him in pursuance of the rules of the society of which he was a member. The insurance practitioner should furnish such certificates at the request of the insured person and any certificates necessary to satisfy the society that arrears were not to be reckoned. The practitioner was, of course, not bound to furnish certificates for the purpose of satisfying the employer as to compensation, but he should supply such certificates as were necessary to enable the insured person to obtain an advance from his society pending the settlement of his claim.

---

[1] THE LANCET, Nov. 1st, p. 1280.

BRISTOL INSURANCE COMMITTEE.

At a recent meeting of the Bristol Insurance Committee some interesting figures were given by the chairman with regard to the work of the committee. At Bristol on July 14th there were 120,058 persons entitled to medical and sanatorium benefits. The addition of deposit contributors out of all benefits brought the figure up to 120,343, or about one-third of the whole population, a net increase of 6173 insured persons. Payment to medical men and institutions had been on account of 96,316 persons who had chosen their medical attendants and 11,304 treated through institutions; 12,723 persons had not chosen their medical men, an increase on the figure (less than 10,000) of a few months earlier. The disposal of a sum of £4453 was thus under consideration, and the chairman supposed it would some day reach the hands of the medical profession. He called attention to the disregard of 10 per cent. of the insured to exercise their right of choice, and expressed regret that the system of payment by incidence of sickness was not adopted by the medical profession at Bristol. This would have meant the distribution of the whole of the panel fund quarter by quarter, money would be earned by work done with less clerical work for the Committee and for the medical men, and there would have been no funds left to quarrel about in the future. He did not know whether it was now possible to change their system of remuneration, but he personally would welcome the alteration, and he believed that it would be for the benefit of the insured persons. The payment to druggists for work done and materials supplied was on a more business-like and satisfactory basis than that with regard to medical attendance, and he believed that the payment of fees for treatment accorded would ensure fewer complaints of perfunctory attendance. He described the capitation system as the voting of salaries, each vote being worth 7*s.* a year to its recipient. There were 117 medical men on the Bristol panel, of whom 61 received less than £200 a year, the average earnings of these amounting to £113. One medical man made over £1100 a year and two made over £1000. Half the divisible fund was shared by 26 medical men with an average of £650 per annum. The remainder was divided between 91, who took from £400 a year to a few sovereigns.

A report of the Medical Benefit Subcommittee on the subject of the medical adviser to the committee showed that after-consultation with the Medical Service Subcommittee it recommended that the services of Dr. Bertram M. H. Rogers should be continued in this capacity for three months, the terms of service being a retaining fee of £82 10*s.*, and that Approved Societies with members in the area be invited not to appoint referees of their own, but to refer all cases through the committee to Dr. Rogers, at a charge of 2*s.* 6*d.* per case referred and 5s. per case examined; that medical men on the panel should also refer cases to him; and that the Commissioners be asked to appoint a permanent medical adviser—this to be, perhaps, eventually a whole-time appointment. The scheme referred to had received provisional approval from the Commissioners. The report was adopted.

Information was laid before the committee with regard to arrangements made by the Sanatorium Benefit Subcommittee for the reception of insured persons nominated by the committee at the Royal National Sanatorium, Bournemouth, at a fee of 30*s.* per week for each patient. Seven persons had been sent to this institution, and arrangements were pending for the sending of four more.

A CONFERENCE OF NON-PANEL MEDICAL SOCIETIES.

A conference of non-panel medical associations will be held in London at the Waldorf Hotel, Kingsway, W.C., on Saturday, Nov. 29th, at 3 P.M.

The National Medical Union, with the assistance of several leading London societies, is responsible for convening this meeting. Invitations are being issued to all known non-panel bodies, and the chief object of the conference is the promotion of the federation of non-panel organisations throughout the country. The promoters aim at making the meeting representative of all non-service practitioners, and secretaries of all such associations and all medical men who are not serving under the National Insurance Act are earnestly requested to communicate with the secretary of the Union, Mr. J. Webster Watts, 5, John Dalton-street, Manchester.

On Nov. 6th, at a meeting of the London Medical Committee, which is entirely non-panel, it was decided to send representatives to the Conference of Non-panel Associations. The committee appointed the chairman, Dr. Fred. J. Smith, Dr. Bernard O'Connor, barrister-at-law, and the honorary secretary, Mr. E. Arthur Dorrell, to be the representatives at the conference. A report was received by the committee that non-panel associations had been formed for Lambeth and for Islington and St. Pancras (combined). Also reports of meetings and of the strength of membership were received from Wandsworth, Hampstead, and Lewisham non-panel associations. A letter was received from a medical man in the Wandsworth district, who has unrivalled opportunity of observing the working of the Insurance Act in the poorer districts, showing how thoroughly the insured dislike the Act and the panel system with its restricted choice of doctor, and how "hundreds of panel patients come to me" either because they will not go to a panel doctor or do not wish to repeat the experience. The committee adjourned until Monday next, Nov. 17th.

ENFIELD LOCAL MEDICAL COMMITTEE.

A meeting of the Enfield Local Medical Committee (recognised as consisting of all the resident practitioners in the area) was held on Nov. 7th, and 12 members were present. The Commissioners' Circular 30/1C was considered, and it was resolved to memorialise the Commissioners in favour of the election of the New Panel Committee for Middlesex by *districts*. It was decided that nomination papers be signed in favour of Dr. J. Busfield, Dr. R. M. Hall, Dr. H. Distin, Dr. F. W. Foott, and Dr. R. L. Ridge, but in the event of election by districts being sanctioned, and two members only being allowed for Enfield, that then the three latter would withdraw their nominations in favour of Dr. Busfield and Dr. Hall.

The honorary secretary was authorised to send the names of these two practitioners to the medical papers as the official nominees of the Local Committee; also to ask general support for these candidates, and to promise the support of Enfield practitioners to the officially recognised candidates of other Local Committees if in proportion to the practitioners in those districts. Dr. Tresilian, Dr. Busfield, and Dr. Ridge were elected as the medical members of the District Insurance Committee.

THE DEATH OF DR. HORACE DIMOCK.

The inquiry into the death of Dr. Dimock was resumed on Wednesday last by the coroner for the Isle of Ely, Mr. Martin Hall, who said that it had been agreed to adjourn the inquest again until Dec. 3rd, Dr. W. H. Willcox requiring a month to complete his analyses.

Revelations have been made as to the persecution to which Mr. H. C. Meacock and other practitioners had been subjected owing to the position which they considered it due to themselves and their profession to take up; and it has now become apparent to the public, as well as to the medical profession, that the legal action taken against the late Dr. Dimock was an absolutely defensive measure supported and conducted by the police. The statutory Local Medical Committee of the Isle of Ely have passed a resolution recording "entire confidence in the honour of its chairman, Mr. H. C. Meacock, and the other medical practitioners of Wisbech, whose characters have been assailed in a most scurrilous and underhand manner," and extending to them and their wives "most sincere sympathy in their recent undeserved trouble."

The panel remains closed to the Wisbech practitioners, Dr. H. G. Baynes having been appointed in the room of the late Dr. Dimock.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held on Nov. 6th at Caxton House, Westminster, with Sir Francis H. Champneys in the chair.—A number of midwives were struck off the roll, the following charges, amongst others, having been brought forward: Having advised that a case was one in which the attendance of a medical practitioner was required, and a medical practitioner being in attendance accordingly, his instructions were not faithfully carried out as required by Rule E 6. Neglect to take the pulse and temperature of patients, as required by Rule E.13; neglect to wash the patient at any time; not being scrupulously clean, being ignorant of antiseptics and having no proper appliances, as required by Rule E.2. That when attending patients the midwife did not wear a clean dress of washable material, as required by Rule E.1. The bag of appliances was dirty, and had no washable lining. Not keeping the Register of Cases as required by Rule E. 23. Medical aid having been sent for, [illegible] thereof to the L [illegible] 21 (1). [illegible] charge fr [illegible] attendan [illegible] she did not hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might be immediately forwarded to the medical practitioner, as required by Rule E. 20 (5).

Medical News.

FOREIGN UNIVERSITY INTELLIGENCE.—*Giessen*: Dr. Alfred Brüggemann has been recognised as [illegible] aryngology.—*Greifswald*: [illegible] ophthalmology, has been [illegible] —*Hamburg*: Dr. J. F. Wiesinger, surgeon to St George's Hospital, Dr. Carl Sick, surgeon to the Eppendorf Hospital, Dr. Hermann Wilbrand, ophthalmic surgeon to St. George's Hospital, and Dr. Max Nonne, physician to the Eppendorf Hospital, have been granted the title of Professor.—*Lausanne*: Dr. Taillens, *privat-docent* of medicine, has been promoted to an Extraordinary Professorship.—*Naples*: Dr. Ermanno Cedrangolo has been recognised as *privat-docent* of Medical Semeiology.

MEDICAL MAYORS.—The following members of the medical profession have been elected or re-elected to the mayoral chair: Mr. J. Robinson, L.R.C.P.I., L.R.C.S.I. (Cardiff, Lord Mayor); Mr. Preston King, M.D., B.C. Cantab. (Bath); Mr. S. Hale Puckle, M.B., Ch.M. Edin. (Bishops Castle); Mr. J. Rafter, L.R.C.P.I., L.R.C.S.I. (Bootle); Mr. S. R. Alexander, M.D. Lond. (Faversham), re-elected; Mr. H. Foster Jeffery, M.B., Ch.B. Vict. (Heywood), re-elected; Mr. W. E. L. Davies, M.R.C.S. Eng., L.R.C.P. Lond. (Llanidloes); Mr. Nicholas W. Fairles-Humphreys, M.R.C.S. Eng. (Montgomery), fifteenth time; Mr. J. L. Davies, M.R.C.S. Eng., L.R.C.P. Lond. (Newport, Mon.); Mr. R. Jones Evans, M.R.C.S. Eng., L.R.C.P. Lond. (Pwllheli); Mr. J. Parkinson Atkinson, M.D. Glasg. (Saffron Walden), re-elected; and Mr. A. W. Limont, M.B., C.M. Edin. (Southport).—Mr. F. W. S. Stone was at the municipal elections at Dover returned at the head of the poll in an important ward. He has been chosen as deputy-mayor.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: SCHOOL MEDICAL OFFICERS.—The first meeting of the School Medical Service group of the Society of Medical Officers of Health was held at 1, Upper Montague-street, London, W.C., the office of the society, on Nov. 7th, under the chairmanship of Dr. Alfred Greenwood. Dr. Robert Hughes, of Stoke-on-Trent, was elected chairman, Dr. Armly Ashkenny as honorary secretary, and Dr. C. W. Hutt, honorary treasurer. The committee of the group consists of the above three *ex-officio* members, together with one member from each of the 10 branches of the Society of Medical Officers of Health. The constitution of the group was discussed, and it was decided that all medical officers engaged in the School Medical Service be invited to join; and assistants in the service will have special consideration, [illegible] condemned as very inadequate considering the long, expensive, and arduous professional training, often lasting for ten years, and the responsible, onerous, and the rapidly increasing duties to be performed. It was pointed out that the Board of Education have admitted the inadequacy of salaries of medical officers in their circular letter to local authorities dated August 18th. Even with the promise of increased grants by the board for medical inspection, local education authorities were not likely to increase the salaries of the medical staff to any considerable extent, as desired by the board, unless all assistant medical officers combined in one body and unitedly claimed just treatment from local authorities. The group meeting therefore passed a resolution to the effect that the Society of Medical Officers of Health recommend the British Medical Association to accept no advertisement for a whole-time assistant school medical officer at a less sum than a commencing salary of £350 per annum. The next meeting of the group will be held on Saturday, Dec. 6th, at 2 P.M., at 1, Upper Montague-street, Russell-square, London, W.C. Assistants in the School Medical Service are requested to send their name and address, and anything that may be of interest to the service to Dr. Armly Ashkenny, honorary secretary, Medical Department, Education Office, Council House, Birmingham.

PATHOLOGICAL UNIVERSITY INSTITUTE, BERLIN.—This institution, of which Dr. Goldscheider is the director, has just been considerably enlarged. The clinical department now contains 56 beds, 15 of which are reserved for hydrotherapeutic treatment. In the out-patient department there are now eight assistant physicians.

A PLYMOUTH CENTENARIAN.—John Ryan died at Plymouth on Oct. 29th in his 104th year. He was born at Thurles, Tipperary, on June 24th, 1810, and went to Plymouth in 1851. He was wonderfully active for his age, and until two weeks previously to his death walked to church every Sunday.

A MEETING will be held on Tuesday, Nov. 18th, at 8.30 P.M., at 11, Chandos-street, W., to discuss the position of medical officers in His Majesty's prisons. The chair will be taken by Dr. W. Hugh Fenton. A resolution will be submitted calling upon the Home Office to cease to require the prison medical officers to act under the direction of the lay authorities in professional matters, and to abandon the practice of forcible feeding, which has proved futile, and which is only continued as a punishment.

GLASGOW UNIVERSITY CLUB, LONDON.—The winter dinner of this club will be held at the Trocadero Restaurant, Piccadilly Circus, on Friday, Nov. 28th, at 7.15 for 7.30 P.M., under the chairmanship of Sir William S. McCormick, secretary to the Carnegie Trust. Members intending to be present or to bring guests should give early notice to the honorary secretaries, Dr. David Roxburgh and Dr. Alexander Macphail, at 30, Seymour-street, London, W.

ROYAL SOCIETY OF ARTS.—The society will commence its 160th session on Nov. 19th with an address delivered at 8 P.M. by Colonel Sir Thomas H. Holdich, K.C M.G. Before Christmas there will be four meetings besides the opening meeting, the subjects and the names of the speakers being as follows: Zoological Gardens, by Dr. Chalmers Mitchell; Perfumery, by Mr. John Umney; Applications of Electricity to Agriculture, by Mr. Thorne Baker; and the Channel Tunnel, by Mr. Arthur Fell. There will be five courses of Cantor Lectures, of which one course consisting of three lectures on the Measurement of Strains in Materials and Structure will be delivered by Professor Coker on Dec. 1st, 8th, and 15th. During the Christmas holidays a course of juvenile lectures on wireless telegraphy will be given by Mr. Howgrave Graham.

ROYAL MEDICAL BENEVOLENT FUND.—At the October meeting of the committee 24 cases were considered and grants amounting to £181 made to 18 of the applicants. Appended is an abstract of the cases relieved :—

Widow, aged 48, of M.R.C.S., L.R.C.P. Practically unprovided for at husband's death 18 months ago, and is endeavouring to support herself by taking boarders. Two daughters, aged 18 and 9, the elder earning 12s. 6d. a week as a clerk, the younger at an institution. Relieved once, £10. Voted £10.—Daughter, aged 61, of late M.R.C.S. Was one of nine children at the death of her father 50 years ago, and for many years supported herself and helped her mother by acting as governess or school matron. Income only a few shillings a week, and is no longer able to obtain remunerative work. Voted £10.—Widow, aged 70, of M.D. Glasgow. Lost her husband six months ago, and finds that owing to depreciation in investments her income will be less than £10 a year. No children or relations able to give permanent help. Voted £18.—Widow, aged 55, of L.R.C.P., L.R.C S Edin. Lost her husband a few months ago after an illness lasting several years, during which she supported the family by taking lodgers. Five children, of whom four are still at school and the eldest has just obtained a bursary at a university. Voted £12.—Widow, aged 50, of M.R.C S. Quite unprovided for at recent death of husband from new growth, but hopes to support herself by obtaining paying guests. Voted £10.—L.S.A., aged 55. Has a very small practice in a London suburb, but has broken down in health and is ordered a holiday which he can ill afford. Voted £5.—Widow, aged 51, of M.D. Edin. Lost her husband some months ago after a long and painful illness which quite exhausted his small savings. Receives 3s. a week from a stepson and takes a lodger. Voted £10.—Widow, aged 46, of L.F.P S. Glasg. Supported herself for several years after her husband's death as a school matron, but was obliged to give up her post on account of progressive deafness. No income, and dependent on a widowed mother whose means are very small. Asks for assistance to cover the expenses of sending her only son in for the examination for a second mate's certificate. Relieved once, £10. Voted £10.—Daughter, aged 68, of late M.R.C.S. Was a nurse for many years, and now has a pension of £20 a year from another society. Relieved three times, £36. Voted £6.—Widow, aged 73, of M.R.C.S. Receives an old-age pension and slight help from her children, but asks for assistance towards expenses incurred through chronic ill-health. Relieved eight times, £96. Voted £12.—Daughter, aged 51, of late M.R.C S. *Has a small house at a low rent, letting rooms in the* summer and making sweets in the winter. Relieved twice, £20. Voted £12.—Daughter, aged 41, of late F.R.C.S. Has a stiff right shoulder-joint, which makes it very difficult to obtain regular and suitable employment. Relieved seven times, £84. Voted £12.—Daughter, aged 54, of late M.R.C.S. Used to be a nurse, but suffers from chronic glaucoma, and is now quite unable to support herself. Slight help from relations. Relieved five times, £45. Voted £10.—Widow, aged 73, of M.R.C.S. Receives an old age pension and 5s. a week from a charitable society. Relieved once, £12. Voted £9.—Widow, aged 47, of M.D. Assists at a boarding-house kept by a widowed sister, but receives no salary, and asks for help towards small expenses unavoidably incurred for her boy, aged 14. Relieved 14 times, £151. Voted £5.—Widow, aged 64, of L.R.C.S., L.R.C.P. Irel. Has a situation as cook, but finds the work so hard that she is obliged to give it up. Proposes to live with a son earning a small weekly wage and having five children. Relieved once, £5. Voted £12.—Daughter, aged 71, of late M.D. Is an inmate at a Home for Incurables, but has no means to meet small unavoidable expenses. Was an annuitant of this Fund until elected to the Home. Voted £6.—Daughter, aged 58, of late M.R.C.S. Is almost blind and entirely dependent upon a friend and the help given by this Fund. Relieved three times, £22. Voted £12.
